Abstract. We give a general account of family algebras over a finitely presented linear operad, this operad together with its presentation naturally defining an algebraic structure on the set of parameters.

1. Introduction

The first family algebra structures appeared in the literature in 2007: a natural example of Rota-Baxter family algebras of weight $-1$ was given by J. Gracia-Bondía, K. Ebrahimi-Fard and F. Patras in a paper on Lie-theoretic aspects of renormalization [8, Proposition 9.1] (see also [14]). The notion of Rota-Baxter family itself was suggested to the authors by Li Guo (see Footnote after Date: May 9, 2020.

2010 Mathematics Subject Classification. 16W99, 16S10, 08B20, 16T30, 17D25.

Key words and phrases. Monoidal categories, graded objects, operads, colored operads, dendriform algebras, duplicial algebras, pre-Lie algebras, typed decorated planar binary trees, diassociative semigroups.
Proposition 9.2 therein), who started a systematic study of these Rota-Baxter family algebras in [12], including the more general case of weight \( \lambda \). They are associative algebras \( P \) over some field \( k \) together with a collection \( (P_\omega)_{\omega \in \Omega} \) of linear endomorphisms indexed by a semigroup \( \Omega \) such that the Rota-Baxter family relation

\[
P_\alpha(a)P_\beta(b) = P_{\alpha\beta}(P_\alpha(a)b + aP_\beta(b) + \lambda ab)
\]

holds for any \( a, b \in R \) and \( \alpha, \beta \in \Omega \). The example in [8] is given by the momentum renormalization scheme: here \( \Omega \) is the additive semigroup of non-negative integers, and the operator \( P_\omega \) associates to a Feynman diagram integral its Taylor expansion of order \( \omega \) at vanishing exterior momenta. The simplest example we can provide, derived from the minimal subtraction scheme, is the algebra of Laurent series \( R = k[\mathbb{Z}, z] \), where, for any \( \omega \in \Omega = \mathbb{Z} \), the operator \( P_\omega \) is the projection onto the subspace \( R_{<\omega} \) generated by \( \{z_k, k < \omega\} \) parallel to the supplementary subspace \( R_{\geq \omega} \) generated by \( \{z_k, k \geq \omega\} \).

Other families of algebraic structures appeared more recently: dendriform and tridendriform family algebras [22, 23, 9], pre-Lie family algebras [16],... The principle consists in replacing each product of the structure by a family of products, so that the operadic relations (Rota-Baxter, dendriform, pre-Lie,....) still hold in a “family” version taking the semigroup structure of the parameter set into account. An important step in understanding family structures in general has been recently done by M. Aguiar, who defined family \( \mathcal{P} \)-algebras for any linear operad \( \mathcal{P} \) [2]. The semigroup \( \Omega \) of parameters must be commutative unless the operad is non-sigma. An important point is that any \( n \)-ary operation gives rise to a family of operations parametrized by \( \Omega^n \). In particular, the natural way to “familize” a binary operation requires two parameters.

The first author recently described a variant of one-parameter dendriform family algebras for which the set \( \Omega \) of parameters in endowed with the very rich structure of extended diassociative semigroup [9]. We follow here the same path for two-parameter dendriform family algebras, where \( \Omega \) is a now a (non-extended) diassociative semigroup. This suggests that the natural algebraic structure of \( \Omega \) is determined in some way by the operad one starts with. This appears to be the case: we define family \( \mathcal{P} \)-algebras for any finitely presented linear operad \( \mathcal{P} \), in a way which depends on the presentation chosen. The definition makes sense when the parameter set \( \Omega \) is endowed with a \( \mathcal{P} \)-algebra structure, where \( \mathcal{P} \) is a set operad determined by \( \mathcal{P} \) and its presentation. Following the lines of M. Aguiar, we define family \( \mathcal{P} \)-algebras indexed by \( \Omega \) as uniform \( \Omega \)-graded \( \mathcal{P} \)-algebras. The notion of \( \Omega \)-graded \( \mathcal{P} \)-algebra, when \( \Omega \) is a \( \mathcal{P} \)-algebra, is defined via color-mixing operads, which are generalizations of the current-preserving operads of [18].

The paper is organized as follows: we investigate one-parameter and two-parameter dendriform family algebras over a fixed base field \( k \) in some detail in Section 2, as well as their duplicial counterparts. We give the definition of a two-parameter dendriform family algebra \( A \) indexed by a diassociative semigroup \( \Omega \). This structure on the index set naturally appears when one asks \( A \otimes k\Omega \) to be a graded dendriform algebra, in the sense that the homogeneous components \((A \otimes k\omega)_{\omega \in \Omega}\) are respected. The further structure of extended diassociative semigroup (EDS) appears for one-parameter dendriform family algebras [9]. The situation for duplicial family is similar but simpler, due to the fact that the duplicial operad is a set operad. The structure which appears on \( \Omega \) is that of duplicial semigroup. Again, a further structure of extended duplicial semigroup (EDuS) appears...
in the one-parameter version.

We also give an example of two-parameter duplicial family algebra in terms of planar binary trees with \( \Omega \times \Omega \)-typed edges, and we prove that planar binary trees with \( \Omega \)-typed edges provide free one-parameter \( \Omega \)-duplicial algebras for any EDuS \( \Omega \). To conclude this section, we give the generating series of the dimensions of the free two-parameter duplicial (or dendriform) family algebra with one generator, when the parameter set \( \Omega \) is finite.

We give a reminder of colored operads in Joyal’s species formalism \([13]\) in Section 3, and give a brief account of graded objects. Following a crucial idea in \([2]\), we describe the uniformization functor \( \mathcal{U} \) from ordinary (monochromatic) operads to colored operads (resp., with the same notations, from a suitable monoidal category to its graded version), and its left-adjoint, the completed forgetful functor \( \mathcal{F} \).

In Section 4, we study the pre-Lie case in some detail. The pre-Lie operad \( \mathcal{P} \) gives rise to four different set operads, namely the associative operad, the twist-associative operad governing Thedy’s rings with \( x(yz) = (yx)z \) \([20]\), an operad built from corollas governing rings with \( x(yz) = y(xz) \) and \( (xy)z = (yx)z \), and finally the Perm operad governing rings with \( x(yz) = y(xz) = (xy)z = (yx)z \), i.e. set-theoretical Perm algebras. This last operad is a quotient of the three others and gives rise to family pre-Lie algebras. Finally, color-mixing operads and the general definition of \( \Omega \)-family algebras are given in Section 5.

**Notation:** In this paper, we fix a field \( k \) and assume that an algebra is a \( k \)-algebra. The letter \( \Omega \) will denote a set of indices, which will be endowed with various structures throughout the article.

### 2. Dendriform and duplicial family algebras

#### 2.1. Two-parameter \( \Omega \)-dendriform algebras

First, we borrow some concepts from the first author’s recent article \([9]\).

**Definition 2.1.** A diassociative semigroup is a triple \((\Omega, \leftarrow, \rightarrow)\), where \( \Omega \) is a set and \( \leftarrow, \rightarrow: \Omega \times \Omega \rightarrow \Omega \) are maps such that, for any \( \alpha, \beta, \gamma \in \Omega \):

1. \( (\alpha \leftarrow \beta) \leftarrow \gamma = \alpha \leftarrow (\beta \leftarrow \gamma) = \alpha \leftarrow (\beta \rightarrow \gamma) \),
2. \( (\alpha \rightarrow \beta) \leftarrow \gamma = \alpha \rightarrow (\beta \leftarrow \gamma) \),
3. \( (\alpha \rightarrow \beta) \rightarrow \gamma = (\alpha \leftarrow \beta) \rightarrow \gamma = \alpha \rightarrow (\beta \rightarrow \gamma) \).

**Example 2.2.** \([9]\)

(a) If \((\Omega, \circ)\) is an associative semigroup, then \((\Omega, \leftarrow, \circ)\) is a diassociative semigroup.
(b) Let \( \Omega \) be a set. For \( \alpha, \beta \in \Omega \), let

\[ \alpha \leftarrow \beta = \alpha, \quad \alpha \rightarrow \beta = \beta. \]

Then \((\Omega, \leftarrow, \rightarrow)\) is a diassociative semigroup denoted by \( \text{DS}(\Omega) \).

**Definition 2.3.** Let \( \Omega \) be a diassociative semigroup with two products \( \leftarrow \) and \( \rightarrow \). A two-parameter \( \Omega \)-dendriform algebra is a family \((A, (\leftarrow, \rightarrow)_{\alpha, \beta})_{\alpha, \beta \in \Omega}\) where \( A \) is a vector space and

\[ \leftarrow, \rightarrow: \Omega A \rightarrow A \]
are bilinear binary products such that for any $x,y,z \in A$, for any $\alpha, \beta \in \Omega$,
\[
(x <_{a,\beta} y) <_{a-\beta, \gamma} z = x <_{a,\beta-\gamma} (y <_{\beta, \gamma} z) + x <_{a,\beta-\gamma} (y >_{\beta, \gamma} z),
\]
(5)
\[
(x >_{a,\beta} y) <_{a-\beta, \gamma} z = x >_{a,\beta-\gamma} (y <_{\beta, \gamma} z),
\]
(6)
\[
x >_{a,\beta-\gamma} (y >_{\beta, \gamma} z) = (x >_{a,\beta} y) >_{a-\beta, \gamma} z + (x <_{a,\beta} y) >_{a-\beta, \gamma} z.
\]

**Remark 2.4.**

(a) If $\Omega$ is a set, we recover the definition of a two-parameter version of matching dendriform algebras [10] when we consider $(\Omega, \leftarrow, \rightarrow)$ as a diassociative semigroup, that is, for any $\alpha, \beta \in \Omega$,
\[
\alpha \leftarrow \beta = \alpha, \quad \alpha \rightarrow \beta = \beta.
\]

(b) If $(\Omega, \otimes)$ is a semigroup, we recover the definition of two-parameter dendriform family algebras given in [2] when we consider
\[
\alpha \leftarrow \beta = \alpha \rightarrow \beta = \alpha \otimes \beta.
\]

Two-parameter $\Omega$-dendriform algebras are related to dendriform algebras and diassociative semigroups by the following proposition:

**Proposition 2.5.** Let $\Omega$ be a set with two binary operations $\leftarrow$ and $\rightarrow$.

(a) Let $A$ be a $k$-vector space and let
\[
<_{a,\beta}, >_{a,\beta} : A \otimes A \rightarrow A
\]
be two families of bilinear binary products indexed by $\Omega \times \Omega$. We define products $<$ and $>$ on the space $A \otimes k\omega$ by:
\[
(7) \quad (x \otimes \alpha) < (y \otimes \beta) = (x <_{a,\beta} y) \otimes (\alpha \leftarrow \beta),
\]
\[
(8) \quad (x \otimes \alpha) > (y \otimes \beta) = (x >_{a,\beta} y) \otimes (\alpha \rightarrow \beta).
\]

If $(A \otimes k\omega, <, >)$ is a dendriform algebra, then (4), (5) and (6) hold.

(b) The following conditions are equivalent:

(i) For any $(A, (<_{a,\beta}, >_{a,\beta})_{a,\beta \in \Omega})$ where $A$ is a $k$-vector space and where (4), (5) and (6) hold, the vector space $A \otimes k\Omega$ endowed with the binary operations $<$ and $>$ defined by (7) and (8) is a dendriform algebra,

(ii) $(\Omega, \leftarrow, \rightarrow)$ is a diassociative semigroup,

(iii) Any $(A, (<_{a,\beta}, >_{a,\beta})_{a,\beta \in \Omega})$ where $A$ is a $k$-vector space and where (4), (5) and (6) hold is a two-parameter $\Omega$-dendriform algebra.

**Proof.** (a). Let us consider the three dendriform axioms:
\[
\begin{align*}
(x \otimes \alpha) < (y \otimes \beta) < (z \otimes \gamma) &= (x \otimes \alpha) < (y \otimes \beta) < (z \otimes \gamma) + (x \otimes \alpha) < (y \otimes \beta) < (z \otimes \gamma), \\
(x \otimes \alpha) > (y \otimes \beta) < (z \otimes \gamma) &= (x \otimes \alpha) > (y \otimes \beta) + (x \otimes \alpha) > (y \otimes \beta) \otimes (x \otimes \alpha) > (y \otimes \beta) > (z \otimes \gamma).
\end{align*}
\]

The first one gives:
\[
(9) \quad (x <_{a,\beta} y) <_{a-\beta, \gamma} z \otimes (\alpha \leftarrow \beta) \leftarrow \gamma = x <_{a,\beta-\gamma} (y <_{\beta, \gamma} z) \otimes (\alpha \leftarrow \gamma)
\]
\[
+ x <_{a,\beta-\gamma} (y >_{\beta, \gamma} z) \otimes (\alpha \rightarrow (\beta \rightarrow \gamma).
\]

Let $f : k\Omega \rightarrow k$ be the linear map sending any $\delta \in \Omega$ to 1. Applying $Id_A \otimes f$ to both sides of (9), we obtain (4). Similarly, the second dendriform axiom gives (5) and the last one gives (6).
(b). (i) $\implies$ (ii). Let us consider the free 2-parameter $\Omega$-dendriform algebra $A$ on three generators $x$, $y$ and $z$ (from the operad theory, such an object exists). Let us fix $\alpha$, $\beta$ and $\gamma$ in $\Omega$. According to the relations defining 2-parameter $\Omega$-dendriform algebras, $x \prec_{\alpha,\beta\rightarrow\gamma} (y \prec_{\beta,\gamma} z)$ and $x \prec_{\alpha,\beta\rightarrow\gamma} (y \succ_{\beta,\gamma} z)$ are linearly independent in $A$. Let $g : A \rightarrow k$ be a linear map such that
\[
g(x \prec_{\alpha,\beta\rightarrow\gamma} (y \prec_{\beta,\gamma} z)) = 1,
g(x \prec_{\alpha,\beta\rightarrow\gamma} (y \succ_{\beta,\gamma} z)) = 0.
\]
Applying $g \otimes Id_{\Omega}$ on both sides of (9), we obtain that there exists a scalar $\lambda$ such that $\lambda(\alpha \leftarrow \beta) \leftarrow \gamma = \alpha \leftarrow (\beta \leftarrow \gamma)$. As $(\alpha \leftarrow \beta) \leftarrow \gamma$ and $\alpha \leftarrow (\beta \leftarrow \gamma)$ are both elements of $\Omega$, necessarily $\lambda = 1$. Using a linear map $h : A \rightarrow k$ such that
\[
h(x \prec_{\alpha,\beta\rightarrow\gamma} (y \prec_{\beta,\gamma} z)) = 0,
h(x \prec_{\alpha,\beta\rightarrow\gamma} (y \succ_{\beta,\gamma} z)) = 1,
\]
we obtain that $(\alpha \leftarrow \beta) \leftarrow \gamma = \alpha \rightarrow (\beta \leftarrow \gamma)$. The other axioms of diassociative semigroups are obtained in the same way from the second and third dendriform axioms.

(ii) $\implies$ (i). If (ii) holds, (9) immediately implies that the first dendriform axiom is satisfied for any $A$. The second and third dendriform axioms are proved in the same way. Finally, (ii) $\iff$ (iii) is obvious. \hfill \Box

Remark 2.6. We recover the ordinary (i.e. one-parameter) definitions of matching dendriform algebras in [10] (resp. dendriform family algebras in [23]) from Definition 2.3 if $\Omega$ is a set with diassociative semigroup structure given by $\alpha \leftarrow \beta = \alpha$ and $\alpha \rightarrow \beta = \beta$ for any $\alpha, \beta \in \Omega$ (resp. if $(\Omega, \otimes)$ is a semigroup with diassociative semigroup structure given by $\alpha \leftarrow \beta = \alpha \otimes \beta$ for any $\alpha, \beta \in \Omega$), if we suppose that $\prec_{\alpha,\beta}$ depends only on $\beta$ and $\succ_{\alpha,\beta}$ depends only on $\alpha$:
\[
\prec_{\alpha,\beta} = \prec_{\beta}, \quad \succ_{\alpha,\beta} = \succ_{\alpha} \quad \text{for } \alpha, \beta \in \Omega.
\]
A general definition of one-parameter dendriform family algebras encompassing both [10] and [25] has been recently proposed by the first author. This requires an extra structure of extended diassociative semigroup (in short, EDS) on the index set $\Omega$, namely two extra binary products $\prec, \succ$ subject to a bunch of compatibility axioms between themselves and with the diassociative structure $(\leftarrow, \rightarrow)$ [9]. More precisely, if $(\Omega, \leftarrow, \rightarrow, \prec, \succ)$ is an extended diassociative semigroup and $(A, (\prec_{\alpha}, \succ_{\alpha})_{\alpha \in \Omega})$ is a one-parameter $\Omega$-dendriform algebra in the sense of [9], then it is a 2-parameter $\Omega$-dendriform algebra with the products
\[
\prec_{\alpha,\beta} = \prec_{\alpha}, \quad \succ_{\alpha,\beta} = \succ_{\alpha} \quad \text{for } \alpha, \beta \in \Omega.
\]
This is an immediate consequence of Proposition 18 of [9] and Proposition 2.5-(a).

2.2. Two-parameter $\Omega$-duplicial algebras. We can mimick step by step the construction of Paragraph 2.1:

Definition 2.7. A duplicial semigroup is a triple $(\Omega, \leftarrow, \rightarrow)$, where $\Omega$ is a set and $\leftarrow, \rightarrow : \Omega \times \Omega \rightarrow \Omega$ are maps such that, for any $\alpha, \beta, \gamma \in \Omega$:
\[
(\alpha \leftarrow \beta) \leftarrow \gamma = \alpha \leftarrow (\beta \leftarrow \gamma),
(\alpha \rightarrow \beta) \leftarrow \gamma = \alpha \rightarrow (\beta \leftarrow \gamma),
(\alpha \rightarrow \beta) \rightarrow \gamma = \alpha \rightarrow (\beta \rightarrow \gamma).
\]

FAMILIES OF ALGEBRAIC STRUCTURES 5
Let $\alpha \leftarrow (\beta \leftarrow \gamma) = (\alpha \leftarrow \beta) \rightarrow \gamma = (\alpha \rightarrow \beta) \rightarrow \gamma$
are always verified in a diassociative semigroup, but are not required in a duplicial semigroup.

**Definition 2.9.** Let $\Omega$ be a duplicial semigroup with two products $\leftarrow$ and $\rightarrow$. A two-parameter $\Omega$-duplicial algebra is a family $(A, (\prec_{\alpha, \beta}, \succ_{\alpha, \beta})_{\alpha, \beta \in \Omega})$ where $A$ is a vector space and
\[
\prec_{\alpha, \beta}, \succ_{\alpha, \beta}: A \otimes A \to A
\]
are bilinear binary products such that for any $x, y, z \in A$, for any $\alpha, \beta \in \Omega$,
\[
\begin{align*}
(11) & \quad (x \prec_{\alpha, \beta} y) \prec_{\alpha - \beta, y} z = x \prec_{\alpha, \beta - y} (y \prec_{\beta, y} z), \\
(12) & \quad (x \succ_{\alpha, \beta} y) \prec_{\alpha - \beta, y} z = x \succ_{\alpha, \beta - y} (y \prec_{\beta, y} z), \\
(13) & \quad x \succ_{\alpha, \beta - y} (y \succ_{\beta, y} z) = (x \succ_{\alpha, \beta} y) \succ_{\alpha - \beta, y} z.
\end{align*}
\]

Two-parameter $\Omega$-duplicial algebras are related to duplicial algebras and duplicial semigroups by the following proposition:

**Proposition 2.10.** Let $\Omega$ be a set with two binary operations $\leftarrow$ and $\rightarrow$.

(a) Let $A$ be a $k$-vector space and let
\[
\prec_{\alpha, \beta}, \succ_{\alpha, \beta}: A \otimes A \to A
\]
be two families of bilinear binary products indexed by $\Omega \times \Omega$. We define products $\prec$ and $\succ$ on the space $A \otimes k\Omega$ by:
\[
\begin{align*}
(14) & \quad (x \otimes \alpha) \prec (y \otimes \beta) = (x \prec_{\alpha, \beta} y) \otimes (\alpha \leftarrow \beta), \\
(15) & \quad (x \otimes \alpha) \succ (y \otimes \beta) = (x \succ_{\alpha, \beta} y) \otimes (\alpha \rightarrow \beta).
\end{align*}
\]
If $(A \otimes k\Omega, \prec, \succ)$ is a duplicial algebra, then (11), (12) and (13) hold.

(b) The following conditions are equivalent:

(i) For any $(A, (\prec_{\alpha, \beta}, \succ_{\alpha, \beta})_{\alpha, \beta \in \Omega})$ where $A$ is a $k$-vector space and where (11), (12) and (13) hold, the vector space $A \otimes k\Omega$ endowed with the binary operations $\prec$ and $\succ$ defined by (14) and (15) is a duplicial algebra,

(ii) $(\Omega, \leftarrow, \rightarrow)$ is a duplicial semigroup,

(iii) Any $(A, (\prec_{\alpha, \beta}, \succ_{\alpha, \beta})_{\alpha, \beta \in \Omega})$ where $A$ is a $k$-vector space and where (4), (5) and (6) hold is a two-parameter $\Omega$-duplicial algebra.

The proof is similar to the proof of Proposition 2.5 and left to the reader.

**Remark 2.11.** A duplicial semigroup is nothing but a duplicial algebra in the monoidal category of sets. Hence the duplicial algebra structure on $A \otimes k\Omega$ together with the $\Omega$-grading yields a duplicial algebra structure on $\Omega$. This property has no equivalent in the dendriform case. It owes to the fact that the duplicial operad is a set operad, whereas the dendriform operad is a linear operad which is not reducible to a set operad. Another occurrence of this phenomenon will be described in greater detail in Section 4 devoted to two-parameter family pre-Lie algebras.

Now we give a concrete example of two-parameter $\Omega$-duplicial algebra, which uses typed decorated planar binary trees [4, 23].

**Definition 2.12.** Let $X$ and $\Omega$ be two sets. An $X$-decorated $\Omega \times \Omega$-typed (abbreviated two-parameter typed decorated) planar binary tree is a triple $T = (T, \text{dec}, \text{type})$, where
(a) $T$ is a planar binary tree.
(b) $\text{dec} : V(T) \rightarrow X$ is a map, where $V(T)$ stands for the set of internal vertices of $T$,
(c) $\text{type} : IE(T) \rightarrow \Omega \times \Omega$ is a map, where $IE(T)$ stands for the set of internal edges of $T$.

**Example 2.13.** Let $X$ and $\Omega$ be two sets. The typed decorated planar binary trees with three internal vertices are

![Diagrams of decorated planar binary trees]

with $x, y, z \in X$ and $(\alpha, \beta), (\gamma, \delta) \in \Omega \times \Omega$.

Denote by $D(X, \Omega)$ the set of two-parameter typed decorated planar binary trees. For any $s \in D(X, \Omega)$ we denote by $\bar{s}$ the subjacent decorated tree, forgetting the types.

**Definition 2.14.** Let $\Omega$ be a set. For $\alpha, \beta \in \Omega$, first define

$$s \prec_{\alpha, \beta} t := \bar{s} < \bar{t} + \text{following types}$$

which means grafting $t$ on $s$ at the rightmost leaf, and the types follow the rules below:

- the new edge is typed by the pair $(\alpha, \beta)$;
- any internal edge of $t$ has its type moved as follows:
  $$(\omega, \tau) \mapsto (\omega, \tau \leftarrow \beta);$$
- any internal edge of $s$ has its type moved as follows:
  $$(\omega, \tau) \mapsto (\alpha \leftarrow \omega, \tau);$$
- other edges keep their types unchanged.

Similarly, we second define

$$s \succ_{\alpha, \beta} t := \bar{s} > \bar{t} + \text{following types}$$

which means grafting $s$ on $t$ at the leftmost leaf, and the types follow the following rules:

- the new edge is typed by the pair $(\alpha, \beta)$;
- any internal edge of $t$ has its type moved as follows:
  $$(\omega, \tau) \mapsto (\alpha \leftarrow \omega, \tau);$$
- any internal edge of $s$ has its type moved as follows:
  $$(\omega, \tau) \mapsto (\omega \rightarrow \beta);$$
- other edges keep their types unchanged.

**Example 2.15.** Let $X$ and $\Omega$ be two sets. Let

$$s = (\alpha_1, \alpha_2) \times (\beta_1, \beta_2), \quad \text{and} \quad t = \times (\beta_1, \beta_2).$$

Then

$$s \succ_{\alpha, \beta} t = (\alpha_1, \alpha_2) \times (\beta_1, \beta_2) \succ_{\alpha, \beta} m \times (\beta_1, \beta_2) = (\alpha_1, \alpha_2 \rightarrow \beta) \times (\alpha_\rightarrow \beta, \beta_2).$$
\[
\begin{align*}
s \prec_{\alpha,\beta} t &= (\alpha_1,\alpha_2) \prec_{\alpha,\beta} \beta_1, \beta_2 \prec_{\alpha,\beta} m (\alpha_1, \alpha_2 \prec_{\beta_1, \beta_2} n (\alpha, \beta) \prec_{\alpha,\beta} \beta_1, \beta_2) \\
m \prec_{\alpha,\beta} n &= (\alpha_1, \alpha_2 \prec_{\beta_1, \beta_2} n (\alpha, \beta) \prec_{\alpha,\beta} \beta_1, \beta_2) \\
\end{align*}
\]

**Proposition 2.16.** Let \( X \) and \( \Omega \) be two sets. The pair \((D(X, \Omega), (\prec_{\alpha,\beta}, \succ_{\alpha,\beta})_{\alpha,\beta \in \Omega})\) is a two-parameter \( \Omega \)-duplicial algebra.

**Proof.** For \( s, t, u \in D(X, \Omega) \) and \( \alpha, \beta, \gamma \in \Omega \), we first prove Eq. (11). Let us look at the right hand side of Eq. (11), that is, \( s \prec_{\alpha,\beta,\gamma} (t \prec_{\beta,\gamma} u) \). We divide the procedure into two steps.

- **First step:** we deal with \( t \prec_{\beta,\gamma} u \), we have the new edge typed by \((\beta, \gamma)\); the edges of \( u \) have their types \((\omega, \tau)\) changed into \((\beta \prec_{\alpha,\beta} \omega, \tau)\); the edges of \( t \) have their types \((\omega, \tau)\) changed into \((\omega, \tau \prec_{\alpha,\beta} \beta)\).
- **Second step:** we deal with \( s \prec_{\alpha,\beta} (t \prec_{\beta,\gamma} u) \), which means grafting \( t \prec_{\beta,\gamma} u \) on the rightmost leaf of \( s \). The new edge has its type \((\alpha, \beta \prec_{\alpha,\beta,\gamma} \gamma)\); the new edge of \( t \prec_{\beta,\gamma} u \) produced in the first step has its type \((\beta, \gamma)\) changed into \((\alpha \prec_{\alpha,\beta,\gamma} \beta, \gamma)\); the edges of \( u \) have their types \((\beta \prec_{\alpha,\beta} \omega, \tau)\) changed into \((\alpha \prec_{\alpha,\beta,\gamma} \beta \prec_{\alpha,\beta} \omega, \tau)\); the edges of \( t \) have their types \((\omega, \tau \prec_{\alpha,\beta} \beta)\) changed into \((\omega, \tau \prec_{\alpha,\beta,\gamma} \beta)\).

Let us now look at the left hand side of Eq. (11), that is, \( (s \prec_{\alpha,\beta} t) \prec_{\alpha,\beta,\gamma} u \). We also divide into the procedure two steps.

- **First step:** we deal with \( s \prec_{\alpha,\beta} t \): we graft \( t \) on \( s \), and the new edge typed by \((\alpha, \beta)\); the edges of \( t \) have their types \((\omega, \tau)\) changed into \((\alpha \prec_{\alpha,\beta} \omega, \tau)\); the edges of \( s \) have their types \((\omega, \tau)\) changed into \((\omega, \tau \prec_{\alpha,\beta} \beta)\).
- **Second step:** we deal with \( (s \prec_{\alpha,\beta} t) \prec_{\alpha,\beta,\gamma} u \). The new edge typed by \((\alpha \prec_{\alpha,\beta} \beta, \gamma)\); the new edge of \( s \prec_{\alpha,\beta} t \) has its type \((\alpha, \beta \prec_{\alpha,\beta,\gamma} \gamma)\); the edges of \( s \) have their types \((\omega, \tau \prec_{\alpha,\beta} \beta)\) changed into \((\omega, (\tau \prec_{\alpha,\beta} \beta \prec_{\alpha,\beta,\gamma} \gamma)\); the edges of \( t \) have their type \((\alpha \prec_{\alpha,\beta,\gamma} \omega, \tau)\) changed into \((\alpha \prec_{\alpha,\beta,\gamma} \omega, \tau \prec_{\alpha,\beta,\gamma} \beta)\); the edges of \( u \) have their types \((\omega, \tau)\) changed into \((\alpha \prec_{\alpha,\beta,\gamma} \beta \prec_{\alpha,\beta,\gamma} \omega, \tau)\).

Comparing both sides and using the duplicial semigroup axioms proves Equation (11).
Second, we prove Equation (12). We use a table for comparison.

<td>the edges of $s$</td>
<td>$(\omega, \tau) \mapsto (\omega, \tau \leftrightarrow \beta)$</td>
</tr>
</tbody>
</table>

So both the left hand side and right hand side coincide.

Last, Eq. (13) can be proved similarly to Eq. (11). Details are left to the reader. □

2.3. Free one-parameter $\Omega$-duplicial algebras. We give a general definition of one-parameter $\Omega$-duplicial algebras in the spirit of [9].

**Definition 2.17.** An extended duplicial semigroup (briefly, EDuS) is a family $(\Omega, \leftarrow, \rightarrow, <, \triangleright)$, where $\Omega$ is a set and $\leftarrow, \rightarrow, <, \triangleright : \Omega \times \Omega \to \Omega$ are maps such that:

(a) $(\Omega, \leftarrow) = (\Omega, \rightarrow)$ is a duplicial semigroup.

(b) For any $\alpha, \beta, \gamma \in \Omega$,

$\alpha \triangleright (\beta \leftarrow \gamma) = (\alpha \rightarrow \beta)$,  

(18) \hspace{1cm} (\alpha \rightarrow \beta) \leftarrow (\alpha \leftarrow \beta) = (\alpha \leftarrow \beta \leftarrow \gamma)$,  

(19) \hspace{1cm} (\alpha \leftarrow \beta) \triangleright (\alpha \leftarrow \beta) = \alpha \triangleright (\beta \leftarrow \alpha)$,  

(20) \hspace{1cm} (\alpha \triangleright (\beta \leftarrow \gamma) \triangleright (\beta \leftarrow \gamma) = (\alpha \rightarrow (\beta \leftarrow \gamma) \triangleright (\beta \leftarrow \gamma)$,  

(21) \hspace{1cm} (\alpha \triangleright (\beta \leftarrow \gamma) \triangleright (\beta \leftarrow \gamma) = (\alpha \rightarrow (\beta \leftarrow \gamma) \triangleright (\beta \leftarrow \gamma)$,  

(22) \hspace{1cm} (\alpha \triangleright (\beta \leftarrow \gamma) \triangleright (\beta \leftarrow \gamma) = (\alpha \rightarrow (\beta \leftarrow \gamma) \triangleright (\beta \leftarrow \gamma)$,  

(23)

**Remark 2.18.** Any extended diassociative semigroup is an extended duplicial semigroup, but among the 10 axioms describing the compatibility between the arrows and the triangles in an extended diassociative semigroup (numbers 4 to 13 in [9]), only six of them survive in an EDuS (numbers 4, 5, 6, 7, 12 and 13).

**Definition 2.19.** Let $(\Omega, \leftarrow, \rightarrow, <, \triangleright)$ be an EDuS. A one-parameter $\Omega$-duplicial algebra is a family $(A, (<_{\alpha})_{\alpha \in \Omega}, (>_{\alpha})_{\alpha \in \Omega})$, where $A$ is a vector space and $<_{\alpha}, >_{\alpha} : A \otimes A \to A$ such that for any
Let \( \Omega \) element denoted by \( 1 \) to the leaves of the tree. For example,

\[
\begin{align*}
(x <_\alpha y) <_\beta z &= x <_{a\beta} (y <_{a\beta} z), \\
(x >_\alpha y) \preceq z &= (x >_\alpha y) <_\beta z, \\
(x >_\alpha y) \succeq z &= (x >_{a\beta} y) >_{a\beta} z.
\end{align*}
\]

Now we describe free one-parameter \( \Omega \)-duplicial algebras in terms of planar binary trees typed by \( \Omega \), that is, for which each internal edge is typed by single element of \( \Omega \). The set of \( \Omega \)-typed \( X \)-decorated planar binary trees is denoted by \( T(X, \Omega) \). We denote by \( T^*(X, \Omega) \) the set of \( \Omega \)-typed \( X \)-decorated planar binary trees different from the trivial tree \( \emptyset \). For any \( n \geq 0 \), the set of \( \Omega \)-typed \( X \)-decorated planar binary trees with \( n \) internal vertices (and \( n + 1 \) leaves) is denoted by \( T_n(X, \Omega) \). So we have

\[
T(X, \Omega) = \bigsqcup_{n \geq 0} T_n(X, \Omega), \quad \quad \quad T^*(X, \Omega) = \bigsqcup_{n \geq 1} T_n(X, \Omega).
\]

For example,

\[
\begin{align*}
T_0(X, \Omega) &= \{ \emptyset \}, \quad T_1(X, \Omega) = \left\{ \begin{array}{c} x \in X \end{array} \right\}, \quad T_2(X, \Omega) = \left\{ \begin{array}{c} y, y \in X, x \in X, \alpha \in \Omega \end{array} \right\}, \\
T_3(X, \Omega) &= \left\{ \begin{array}{c} y \beta x, y \beta x, y \beta x, y \beta x, y \beta x, y \beta x, y \beta x, \ldots \end{array} \right\}, \quad x, y, z \in X, \alpha, \beta \in \Omega.
\end{align*}
\]

The depth \( \text{dep}(T) \) of a rooted tree \( T \) is the maximal length of linear chains of vertices from the root to the leaves of the tree. For example,

\[
\text{dep}(\begin{array}{c} x \end{array}) = 1 \quad \text{and} \quad \text{dep}(\begin{array}{c} y \alpha \end{array}) = 2.
\]

**Definition 2.20.** Let \( T_1, T_2 \in T(X, \Omega) \), and \( \alpha, \beta \in \Omega \). We denote by \( T_1 \lor_{x, (\alpha, \beta)} T_2 \) the tree \( T \in T(X, \Omega) \) obtained by grafting \( T_1 \) and \( T_2 \) on a common root. If \( T_1 \neq \emptyset \), the type of the internal edge between the root of \( T \) and the root of \( T_1 \) is \( \alpha \). If \( T_2 \neq \emptyset \), the type of internal edge between the root of \( T \) and the root of \( T_2 \) is \( \beta \). We also decorate the new vertex by \( x, z \in X \).

**Remark 2.21.** Note that any element \( T \in T_n(X, \Omega) \), with \( n \geq 1 \), can be written under the form

\[
T = T_1 \lor_{x, (\alpha, \beta)} T_2,
\]

with \( T_1, T_2 \in T(X, \Omega) \), \( x \in X \) and \( \alpha, \beta \in \Omega \). This writing is unique except if \( T_1 = \emptyset \) or \( T_2 = \emptyset \): in this case, one can change arbitrarily \( \alpha \) or \( \beta \). In order to solve this notational problem, we add an element denoted by \( 1 \) to \( \Omega \) and we shall always assume that if \( T_1 = \emptyset \), then \( \alpha = 1 \); if \( T_2 = \emptyset \), then \( \beta = 1 \).

**Definition 2.22.** Let \( \Omega \) be a set with four products \( \langle, \rangle, \leftarrow, \rightarrow \). We define binary operations \( (\langle, \rangle)_{\alpha \in \Omega} \) on \( kT^*(X, \Omega) \) recursively on \( \text{dep}(T) + \text{dep}(U) \) by

(a) \( T \leftarrow \omega U := T \lor_{x, (\alpha, \beta)} U \) for \( \omega \in \Omega \) and \( T \in T^*(X, \Omega) \).

(b) For \( T = T_1 \lor_{x, (\alpha_1, \beta_1)} T_2 \) and \( U = U_1 \lor_{y, (\beta_1, \beta_2)} U_2 \), define

\[
\begin{align*}
T \leftarrow_{\omega} U &= T_1 \lor_{x, (\alpha_1, \alpha_2 + \omega)} (T_2 \leftarrow_{\alpha_2 \omega} U), \\
T \rightarrow_{\omega} U &= (T \rightarrow_{\omega \beta_1} U_1) \lor_{y, (\omega \beta_1, \beta_2)} U_2, \quad \text{where } \omega \in \Omega.
\end{align*}
\]
In the following, we employ the convention that
\[(29) \quad \omega > 1 = 1 < \omega = \omega \quad \text{and} \quad \omega \to 1 = 1 \leftarrow \omega = \omega \quad \text{for} \quad \omega \in \Omega.\]

**Example 2.23.** Let \( T = \begin{array}{c}
\text{x} \\
\end{array} \) and \( U = \begin{array}{c}
\text{y} \\
\end{array} \) with \( x, y \in X \). For \( \omega \in \Omega \), we have
\[
T \prec_\omega U = \begin{array}{c}
\text{x} \\
\text{y} \\
\end{array} \prec_\omega \begin{array}{c}
\text{y} \\
\end{array} = \left( \left\lfloor \vee_{x,(1,1)} \right\rfloor \right) \prec_\omega \begin{array}{c}
\text{y} \\
\end{array} = \begin{array}{c}
\left\lfloor \vee_{x,(1,1)} \right\rfloor \\
\text{y} \\
\end{array} ,
\]
\[
T \succ_\omega U = \begin{array}{c}
\text{x} \\
\text{y} \\
\end{array} \succ_\omega \begin{array}{c}
\text{y} \\
\end{array} = \begin{array}{c}
\text{x} \\
\end{array} \succ_\omega \left( \left\lfloor \vee_{y,(1,1)} \right\rfloor \right) = \left( \left\lfloor \vee_{y,(1,1)} \right\rfloor \right) \begin{array}{c}
\text{y} \\
\end{array}.
\]

**Proposition 2.24.** Let \( X \) be a set and let \( (\Omega, \prec, \succ, \triangleleft, \triangleright) \) be an EDuS. Then \( (kT^+(X, \Omega), (\prec_\omega, \succ_\omega) \}_{\omega \in \Omega} \) is an \( \Omega \)-duplicial algebra.

**Proof.** Let
\[
T = T_1 \vee_{x,(a_1,a_2)} T_2, \quad U = U_1 \vee_{y,(b_1,b_2)} U_2, \quad W = W_1 \vee_{z,(y_1,y_2)} W_2 \in kT^+(X, \Omega).
\]
Then we apply induction on \( \text{dep}(T) + \text{dep}(U) + \text{dep}(W) \geq 3 \). For the initial step \( \text{dep}(T) + \text{dep}(U) + \text{dep}(W) = 3 \), we have
\[
T = \begin{array}{c}
\text{x} \\
\end{array} \quad U = \begin{array}{c}
\text{y} \\
\end{array} \quad \text{and} \quad W = \begin{array}{c}
\text{z} \\
\end{array}
\]
and so
\[
(T \prec_\alpha U) \prec_\beta W = \left( \left\lfloor \vee_{x,(1,1)} \right\rfloor \prec_\alpha \begin{array}{c}
\text{y} \\
\end{array} \right) \prec_\beta \begin{array}{c}
\text{z} \\
\end{array} = \begin{array}{c}
\text{x} \\
\text{y} \\
\end{array} \prec_\beta \begin{array}{c}
\text{z} \\
\end{array} \quad \text{(by Example 2.23)}
\]
\[
\left( \left\lfloor \vee_{x,(1,1)} \right\rfloor \prec_\alpha \begin{array}{c}
\text{y} \\
\end{array} \right) \prec_\beta \begin{array}{c}
\text{z} \\
\end{array} = \left( \left\lfloor \vee_{x,(1,1)} \right\rfloor \right) \left( \left\lfloor \vee_{y,(1,1)} \right\rfloor \right) \left( \left\lfloor \vee_{z,(1,1)} \right\rfloor \right) \quad \text{(by Eq. (27))}
\]
\[
\left( \left\lfloor \vee_{x,(1,1)} \right\rfloor \prec_\alpha \begin{array}{c}
\text{y} \\
\end{array} \right) \prec_\beta \begin{array}{c}
\text{z} \\
\end{array} = \left( \left\lfloor \vee_{x,(1,1)} \right\rfloor \right) \left( \left\lfloor \vee_{y,(1,1)} \right\rfloor \right) \left( \left\lfloor \vee_{z,(1,1)} \right\rfloor \right) \quad \text{(by Example 2.23)}
\]
\[
\left( \left\lfloor \vee_{x,(1,1)} \right\rfloor \prec_\alpha \begin{array}{c}
\text{y} \\
\end{array} \right) \prec_\beta \begin{array}{c}
\text{z} \\
\end{array} = \begin{array}{c}
\text{x} \\
\end{array} \prec_\alpha \begin{array}{c}
\text{y} \\
\end{array} \prec_\beta \begin{array}{c}
\text{z} \\
\end{array} \quad \text{(by Eq. (27))}
\]
\[
\left( \left\lfloor \vee_{x,(1,1)} \right\rfloor \prec_\alpha \begin{array}{c}
\text{y} \\
\end{array} \right) \prec_\beta \begin{array}{c}
\text{z} \\
\end{array} = \begin{array}{c}
\text{x} \\
\end{array} \prec_\alpha \begin{array}{c}
\text{y} \\
\end{array} \prec_\beta \begin{array}{c}
\text{z} \\
\end{array} \quad \text{(by Example 2.23)}
\]
\[
verifying \text{Eq. (24). Next,}
\]
\[
T \succ_\alpha (U \prec_\beta W) = \begin{array}{c}
\text{x} \\
\end{array} \succ_\alpha \left( \left\lfloor \vee_{y,(1,1)} \right\rfloor \prec_\alpha \begin{array}{c}
\text{z} \\
\end{array} \right) = \begin{array}{c}
\text{x} \\
\end{array} \succ_\alpha \left( \left\lfloor \vee_{y,(1,1)} \right\rfloor \right) \prec_\alpha \begin{array}{c}
\text{z} \\
\end{array} \quad \text{(by Example 2.23)}
\]
This completes the proof of the initial step. For the induction step of \( \text{dep}(T) + \text{dep}(U) + \text{dep}(W) = k + 1 \geq 4 \). First, we have

\[
(T \prec_a U) \prec_\beta W = \left( T_1 \lor_{x,(a_1,a_2)} T_2 \right) \prec_a U \prec_\beta W
\]

\[
= \left( T_1 \lor_{x,(a_1,a_2)} T_2 \right) \prec_\beta W \quad \text{(by Eq. (27))}
\]

\[
= T_1 \lor_{x,(a_1,a_2)} T_2 \prec (a_2 < a_1 \lor \beta) W \quad \text{(by Eq. (27))}
\]

\[
= T_1 \lor_{x,(a_1,a_2)} T_2 \prec (a_2 < a_1 \lor \beta) W \quad \text{(by the induction hypothesis)}
\]

\[
= T_1 \lor_{x,(a_1,a_2)} T_2 \prec (a_2 < a_1 \lor \beta) (U < \alpha \lor \beta) W
\]

\[
= (T_1 \lor_{x,(a_1,a_2)} T_2) \prec (a_2 < a_1 \lor \beta) (U < \alpha \lor \beta) W
\]

\[
= (T_1 \lor_{x,(a_1,a_2)} T_2) \prec (a_2 < a_1 \lor \beta) (U < \alpha \lor \beta) W
\]
\[
= T <_{\alpha,\beta} (U <_{\alpha,\beta} W).
\]

Second, we have
\[
T >_{\alpha} (U <_{\beta} W) = T >_{\alpha} \left( (U_1 \lor y, (\beta_1, \beta_2) U_2) <_{\beta} W \right)
= T >_{\alpha} \left( U_1 \lor y, (\beta_1, \beta_2) (U_2 <_{\beta_1} W) \right) \quad \text{(by Eq. (28))}
= (T >_{\alpha} U_1) \lor y, (\alpha \rightarrow \beta_1, \beta_2) U_2 <_{\beta} W \quad \text{(by Eq. (27))}
= \left( (T >_{\alpha} U_1) \lor y, (\alpha, \beta_1, \beta_2) U_2 \right) <_{\beta} W
= (T >_{\alpha} U) <_{\beta} W.
\]

Last, we have
\[
T >_{\alpha} (U >_{\beta} W) = T >_{\alpha} \left( U >_{\beta} (W_1 \lor z, (\gamma_1, \gamma_2) W_2) \right)
= T >_{\alpha} \left( (U >_{\beta \lor \gamma_1} W_1) \lor z, (\beta \rightarrow \gamma_1, \gamma_2) W_2 \right) \quad \text{(by Eq. (28))}
= (T >_{\alpha} (U >_{\beta \lor \gamma_1} W_1)) \lor z, (\alpha \rightarrow (\beta \rightarrow \gamma_1), \gamma_2) W_2 \quad \text{(by Eq. (28))}
= (T >_{(\alpha \rightarrow (\beta \rightarrow \gamma_1)) \lor (\beta \rightarrow \gamma_1)} U) \lor z, (\alpha \rightarrow (\beta \rightarrow \gamma_1), \gamma_2) W_2 \quad \text{(by the induction hypothesis)}
= \left( (T >_{\alpha \lor \beta} U) \lor (\alpha \rightarrow \gamma_1) W_1 \right) \lor z, (\alpha \rightarrow (\beta \rightarrow \gamma_1), \gamma_2) W_2
= (T >_{\alpha \lor \beta} U) >_{\alpha \rightarrow \beta} (W_1 \lor z, (\gamma_1, \gamma_2) W_2)
= (T >_{\alpha \lor \beta} U) >_{\alpha \rightarrow \beta} W.
\]

This completes the proof. \(\Box\)

**Definition 2.25.** Let \(X\) be a set and let \((\Omega, \rightarrow, \alpha, \rho)\) be an EDuS. A free \(\Omega\)-duplicial algebra on \(X\) is an \(\Omega\)-duplicial algebra \((D, (\prec, \succ)_{\omega \in \Omega})\) together with a map \(j : X \rightarrow D\) that satisfies the following universal property: for any \(\Omega\)-duplicial algebra \((D', (\prec', \succ')_{\omega \in \Omega})\) and map \(f : X \rightarrow D'\), there is a unique \(\Omega\)-duplicial algebra morphism \(\tilde{f} : D \rightarrow D'\) such that \(f = \tilde{f} \circ j\). The free \(\Omega\)-duplicial algebra on \(X\) is unique up to isomorphism.

Let \(j : X \rightarrow kT^+(X, \Omega)\) be the map defined by \(j(x) = \bigvee x\) for \(x \in X\).

**Theorem 2.26.** Let \(X\) be a set and let \((\Omega, \rightarrow, \alpha, \rho)\) be an EDuS. Then \((kT^+(X, \Omega), (\prec, \succ)_{\omega \in \Omega})\), together with the map \(j\), is the free \(\Omega\)-duplicial algebra on \(X\).

**Proof.** By Proposition 2.16, we are left to show that \((kT^+(X, \Omega), (\prec, \succ)_{\omega \in \Omega})\) satisfies the universal property. For this, let \((D, (\prec', \succ')_{\omega \in \Omega})\) be an \(\Omega\)-duplicial algebra.

Now let us define a linear map
\[
\tilde{f} : \begin{cases} 
(kT^+(X, \Omega) & \rightarrow D \\
T & \iff \tilde{f}(T)
\end{cases}
\]
by induction on \(\text{dep}(T) \geq 1\). Let us write \(T = T_1 \lor x, (\alpha_1, \alpha_2) T_2\) with \(x \in X\) and \(\alpha_1, \alpha_2 \in \Omega\). For the initial step \(\text{dep}(T) = 1\), we have \(T = \bigvee x\) for some \(x \in X\) and define
\[
(30) \quad \tilde{f}(T) := f(x).
\]
We define $\tilde{f}(T)$ by the induction on $\text{dep}(T) = k + 1 \geq 2$. Note that $T_1$ and $T_2$ can not be $|$ simultaneously and define
\[
\tilde{f}(T) := \tilde{f}(T \lor_{x, (\alpha_1, \alpha_2)} T_2)
\]
\[= \begin{cases} 
  f(x) \prec_{\tau_2} \tilde{f}(T_2), & \text{if } T_1 = | \neq T_2; \\
  \tilde{f}(T_1) \prec_{\tau_1} f(x), & \text{if } T_1 \neq | = T_2; \\
  (\tilde{f}(T_1) \prec_{\tau_2} f(x)) \prec_{\tau_2} \tilde{f}(T_2), & \text{if } T_1 \neq | \neq T_2.
\end{cases}
\] (31)

We are left to prove that $\tilde{f}$ is a morphism of $\Omega$-duplicial algebras:
\[
\tilde{f}(T \prec U) = \tilde{f}(T) \prec \tilde{f}(U) \quad \text{and} \quad \tilde{f}(T \succ U) = \tilde{f}(T) \succ \tilde{f}(U),
\]
in which we only prove the first equation by induction on $\text{dep}(T) + \text{dep}(U) \geq 2$, as the proof of the second one is similar. Write
\[T =_1 \lor_{x, (\alpha_1, \alpha_2)} T_2 \quad \text{and} \quad U = U_1 \lor_{y, (\beta_1, \beta_2)} U_2.
\]
For the initial step $\text{dep}(T) + \text{dep}(U) = 2$, we have $T = \begin{array}{c} x \end{array}$ and $U = \begin{array}{c} y \end{array}$ for some $x, y \in X$. So we have
\[
\tilde{f}(T \prec U) = \tilde{f}(\begin{array}{c} x \end{array} \prec_{\omega} \begin{array}{c} y \end{array}) = \tilde{f}(\begin{array}{c} x \end{array} \prec_{\omega} \begin{array}{c} y \end{array}) \quad \text{(by Example 2.23)}
\]
\[= \tilde{f}(\begin{array}{c} x \end{array} \prec_{\omega} \begin{array}{c} y \end{array}) \quad \text{(by Eq. (31))}
\]
\[= \tilde{f}(\begin{array}{c} x \end{array} \prec_{\omega} \begin{array}{c} y \end{array}) \quad \text{(by Eq. (30))}
\]
\[= \tilde{f}(T) \prec_{\omega} \tilde{f}(U).
\]
For the induction step of $\text{dep}(T) + \text{dep}(U) \geq 3$, we have four cases to consider.

**Case 1:** $T_1 = |$ and $T_2 = |$. Then
\[
\tilde{f}(T \prec U) = \tilde{f}(\begin{array}{c} x \end{array} \prec_{\omega} \begin{array}{c} y \end{array}) \quad \text{(by Eq. (27))}
\]
\[= \tilde{f}(\begin{array}{c} x \end{array} \prec_{\omega} \begin{array}{c} y \end{array}) \quad \text{(by Eq. (31))}
\]
\[= \tilde{f}(T) \prec_{\omega} \tilde{f}(U).
\]

**Case 2:** $T_1 = |$ and $T_2 \neq |$. Then
\[
\tilde{f}(T \prec U) = \tilde{f}(\begin{array}{c} x \end{array} \prec_{\omega} \begin{array}{c} y \end{array}) \quad \text{(by Eq. (27))}
\]
\[= \tilde{f}(\begin{array}{c} x \end{array} \prec_{\omega} \begin{array}{c} y \end{array}) \quad \text{(by Eq. (31))}
\]
\[= \tilde{f}(T) \prec_{\omega} \tilde{f}(U) \quad \text{(by the induction hypothesis)}
\]
\[\quad = \left( f(x) \prec_{\tau_2} \tilde{f}(T_2) \right) \prec_{\omega} \tilde{f}(U) \quad \text{(by Eq. (24))}
\]
\[\quad = \tilde{f}(T) \prec_{\omega} \tilde{f}(U) \quad \text{(by Eq. (31)).}
\]

**Case 3:** $T_1 \neq |$ and $T_2 = |$. This case is similar to Case 2.
Case 4: $T_1 \neq |$ and $T_2 \neq |$. Then
\\[ \tilde{f}(T <_\omega U) = \tilde{f}(T_1 \lor_{x,(a_1, a_2)} T_2 <_\omega U) \]
\\[ = \tilde{f}(T_1 \lor_{x,(a_1, a_2, \omega)} (T_2 <_{a_2 \omega} U)) \quad (\text{by Eq. (27)}) \]
\\[ = (\tilde{f}(T_1) >'_{a_1} f(x)) <'_{a_2 \omega} \tilde{f}(T_2 <_{a_2 \omega} U) \quad (\text{by Eq. (31)}) \]
\\[ = (\tilde{f}(T_1) >'_{a_1} f(x)) <'_{a_2 \omega} (\tilde{f}(T_1) <'_{a_2 \omega} \tilde{f}(U)) \quad (\text{by the induction hypothesis}) \]
\\[ = \tilde{f}(T_1) >'_{a_1} (f(x) <'_{a_2 \omega} \tilde{f}(T_2 <_{a_2 \omega} U)) \quad (\text{by Eq. (25)}) \]
\\[ = \tilde{f}(T_1) >'_{a_1} (f(x) <'_{a_2 \omega} \tilde{f}(T_2)) <'_{a_2 \omega} \tilde{f}(U) \quad (\text{by Eq. (25)}) \]
\\[ = (\tilde{f}(T_1) >'_{a_1} f(x)) <'_{a_2 \omega} \tilde{f}(T_2) <'_{a_2 \omega} \tilde{f}(U) \quad (\text{by Eq. (25)}) \]
\\[ = \tilde{f}(T) <'_{a_1} \tilde{f}(U) \quad (\text{by Eq. (31)}). \]

Let us prove the uniqueness of $\tilde{f}$. Let $\bar{g}$ be another morphism from $kT^+(X, \Omega)$ to $D$ such that $\bar{g}(\bigvee) = f(x)$. First, for any $a \in D$ and $\omega \in \Omega$, we define
\\[ a >'_\omega 1 = 1 <'_\omega a = 0, \quad 1 >'_\omega a = a <'_\omega 1 = a. \]
For any $T \neq |$, let $T = T_1 \lor_{x,(a_1, a_2)} T_2$. In fact, the form $T = T_1 >'_{a_1} \bigvee \lor <'_{a_2} T_2$ include all the above four cases. We define
\\[ \bar{g}(|) = 1 \]
and
\\[ \bar{g}(T) = \bar{g}(T_1 >'_{a_1} \bigvee \lor <'_{a_2} T_2) = \bar{g}(T_1) >'_{a_1} f(x) <'_{a_2} \bar{g}(T_2). \]
So $\tilde{f} = \bar{g}$. This completes the proof. \hfill \Box

**Proposition 2.27.** Let $\Omega$ be an EDuS. Then $(kT^+(X, \Omega) \otimes k\Omega, <, >)$ is a duplicial algebra, if and only if, $(kT^+(X, \Omega), (<_{\omega}, >_{\omega}), \alpha, \beta, \gamma)_{\alpha, \beta, \gamma \in \Omega}$ is an $\Omega$-duplicial algebra, where
\\[ (x \otimes \alpha) < (y \otimes \beta) := (x <_{\alpha \beta} y) \otimes (\alpha \leftarrow \beta) \]
\\[ (x \otimes \alpha) > (y \otimes \beta) := (x >_{\alpha \beta} y) \otimes (\alpha \rightarrow \beta), \quad \text{for } x, y \in T^+(X, \Omega) \text{ and } \alpha, \beta, \gamma \in \Omega. \]

**Proof.** For $x, y, z$ in the $\Omega$-duplicial algebra $T^+(X, \Omega)$ and for $\alpha, \beta, \gamma \in \Omega$, first, we prove
\\[ \left( (x \otimes \alpha) < (y \otimes \beta) \right) < (z \otimes \gamma) \]
\\[ = (x <_{\alpha \beta} y) \otimes (\alpha \leftarrow \beta) < (z \otimes \gamma) \]
\\[ = (x <_{\alpha \beta} y) <_{(\alpha \leftarrow \beta) \circ \gamma} z \otimes (\alpha \leftarrow \beta) \leftrightarrow \gamma) \]
\\[ = x <_{(\alpha \beta) \circ \gamma} (y <_{(\alpha \beta) \circ \gamma} z) \otimes (\alpha \leftarrow \beta) \leftrightarrow (\alpha \leftarrow \beta) \leftrightarrow \gamma) \quad (\text{by Eq. (24)}) \]
\\[ = x <_{\alpha \beta} (y <_{\beta} z) \otimes (\alpha \leftarrow (\beta \leftrightarrow \gamma)) \quad (\text{by Eqs. (20-21) and Definition (2.7)}) \]
\\[ = x \otimes \alpha < (y \otimes \beta) < (z \otimes \gamma) \]
\\[ = (x \otimes \alpha) < (y \otimes \beta) < (z \otimes \gamma). \]
Second, we have

\[(x \otimes a) > (y \otimes \beta) < (z \otimes \gamma)\]

\[= (x \otimes a) > (y <_{\beta,\gamma} z \otimes (\beta \leftarrow \gamma))\]

\[= x >_{\alpha, (\beta \rightarrow \gamma)} (y <_{\beta,\gamma} z) \otimes (\alpha \rightarrow (\beta \leftarrow \gamma))\]  \hspace{1cm} \text{(by Eq. (25))}

\[= x >_{\alpha, \beta} (y <_{(\alpha \rightarrow \beta),\gamma} z) \otimes (\alpha \rightarrow (\beta \leftarrow \gamma))\]  \hspace{1cm} \text{(by Eqs. (18-19) and Definition (2.7))}

Finally, we have

\[(x \otimes a) > (y \otimes \beta) > (z \otimes \gamma)\]

\[= x \otimes a > (y >_{\beta,\gamma} z \otimes (\beta \rightarrow \gamma))\]

\[= x >_{\alpha, (\beta \rightarrow \gamma)} (y >_{\beta,\gamma} z) \otimes (\alpha \rightarrow (\beta \rightarrow \gamma))\]  \hspace{1cm} \text{(by Eq. (26))}

\[= (x >_{(\alpha \rightarrow (\beta \rightarrow \gamma)),\beta,\gamma} y) >_{(\alpha \rightarrow (\beta \rightarrow \gamma)),\beta,\gamma} z \otimes (\alpha \rightarrow (\beta \rightarrow \gamma))\]  \hspace{1cm} \text{(by Eqs. (22-23) and Definition (2.7))}

\[= (x >_{\alpha, \beta} y \otimes (\alpha \rightarrow (\beta \rightarrow \gamma)) > (z \otimes \gamma)\]

\[= (x \otimes a) > (y \otimes \beta) > (z \otimes \gamma).\]

The converse comes from the fact that all axioms of an EDuS have been used in the proof. \hfill \Box

2.4. **On the operads of two-parameter duplicial or dendriform algebras.** Let us assume that the parameter set $\Omega$ is finite, and let us denote its cardinality by $w$. We denote by $\text{Dend}_\Omega^2$, respectively $\text{Dup}_\Omega^2$, the non-sigma operad of two-parameter dendriform, respectively duplicial, algebras.

**Proposition 2.28.** For all $n \geq 1$, we put

\[r_n = \dim_k(\text{Dend}_\Omega^2(n)) = \dim_k(\text{Dup}_\Omega^2(n)),\]

and we consider

\[R(X) = \sum_{n=1}^{\infty} r_n X^n \in \mathbb{Q}[[X]].\]

Then

\[(32) \quad w^2(w - 1)R^3 + w(wX + 2w - 2)R^2 + (2wX - 1)R + X = 0.\]

**Proof.** With a presentation by generators and relations of $\text{Dend}_\Omega^2$ and $\text{Dup}_\Omega^2$, it turns out that these operads own a basis of planar binary trees the vertices of which are decorated by elements $<_a, \beta$ or
$\succ_{\alpha\beta}$, with $\alpha, \beta \in \Omega$, avoiding the trees of the form:

\[
\begin{array}{c}
\alpha, \beta \\
\searrow \quad \searrow \\
\alpha \beta, \gamma \\
\downarrow \\
\alpha, \beta, \gamma
\end{array}
\quad
\begin{array}{c}
\alpha, \beta \\
\nearrow \quad \nearrow \\
\alpha \beta, \gamma \\
\downarrow \\
\alpha, \beta, \gamma
\end{array}
\quad
\begin{array}{c}
\alpha, \beta \\
\nearrow \quad \nearrow \\
\alpha \beta, \gamma \\
\downarrow \\
\alpha, \beta, \gamma
\end{array}
\quad
\begin{array}{c}
\alpha, \beta \\
\searrow \quad \searrow \\
\alpha \beta, \gamma \\
\downarrow \\
\alpha, \beta, \gamma
\end{array}
\quad
\begin{array}{c}
\alpha, \beta \\
\searrow \quad \searrow \\
\alpha \beta, \gamma \\
\downarrow \\
\alpha, \beta, \gamma
\end{array}
\]

with $\alpha, \beta, \gamma \in \Omega$. We denote by $R_<$ the formal series of such trees with root decorated by an element $<_{\alpha\beta}$ and by $R_>$ the formal series of such trees with root decorated by an element $\succ_{\alpha\beta}$, counted according to their number of leaves. Then:

\[
\begin{align*}
R_< &= w^2(R_< + X)R + w(w - 1)R_<R = w^2R^2 - wR_\succ R, \\
R_\succ &= w^2XR + w(w - 1)(R_\succ + R_<)R = w^2R^2 - w(R - X)R, \\
R &= X + R_< + R_>.
\end{align*}
\]

We obtain that:

\[
R_\succ = \frac{w^2R^2}{1 + wR}, \quad R_< = w(w - 1)R^2 + wXR.
\]

Replacing in $R = R_< + R_\succ + X$, we obtain (32).

For example:

\[
\begin{align*}
r_1 &= 1, \\
r_2 &= 2w^2, \\
r_3 &= w^3(8w - 3), \\
r_4 &= 2w^4(20w^2 - 15w + 2), \\
r_5 &= w^5(224w^3 - 252w^2 + 75w - 5), \\
r_6 &= 2w^6(672w^4 - 1008w^3 + 476w^2 - 77w + 3), \\
r_7 &= w^7(8448w^5 - 15840w^4 + 10320w^3 - 2772w^2 + 280w - 7), \\
r_8 &= 2w^8(27456w^6 - 61776w^5 + 51480w^4 - 19635w^3 + 3420w^2 - 234w + 4).
\end{align*}
\]
Remark 2.29. If \( w = 1 \), one recovers duplicial and dendriform algebras, and \( r_n(1) \) is the \( n + 1 \) Catalan number \( \text{Cat}_{n+1} \), sequence A000108 of the OEIS [19]. The sequences \( r_n(w) \) for \( w = 2, 3 \) or 4 are not referenced (yet) in the OEIS.

Proposition 2.30. Let \( n \geq 1 \).

(a) \( r_n \) is a polynomial in \( \mathbb{Z}[w] \), of degree \( 2n - 2 \), and its leading coefficient is \( 2^{n-1} \text{Cat}_n \).

(b) If \( n \geq 2 \), there exists a polynomial \( t_n \in \mathbb{Z}[w] \), such that \( r_n = w^n t_n \). Moreover, \( t_n(0) = (-1)^n n \).

Proof. By (32), if \( n \geq 2 \),

\[
\begin{align*}
 r_n &= w^2 (w - 1) \sum_{i+j+k=n} r_i r_j r_k + w^2 \sum_{i+j=n-1} r_i r_j + w(2w - 2) \sum_{i+j=n} r_i r_j + 2w r_{n-1}. \\

ev'll explain the reasoning and steps here.
\end{align*}
\]

Let us proceed by induction on \( n \). The results are obvious if \( n \leq 3 \). Let us assume that \( n \geq 4 \) and the results at all ranks \( < n \). By (33), obviously \( r_n \in \mathbb{Z}[w] \). Moreover, by the induction hypothesis:

- The first term of (33) is of degree \( \leq 3 + 2n - 6 = 2n - 3 \).
- The second term of (33) is of degree \( \leq 2 + 2n - 6 = 2n - 4 \).
- The third term of (33) is of degree \( \leq 2 + 2n - 4 = 2n - 2 \); its coefficient of degree \( 2n - 2 \) is
  \[
  2 \sum_{i+j=n} 2^{i-1} \text{Cat}_i 2^{j-1} \text{Cat}_j = 2^{n-1} \sum_{i+j=n} \text{Cat}_i = 2^{n-1} \text{Cat}_n.
  \]
- The fourth term of (33) is of degree \( \leq 1 + 2n - 4 = 2n - 3 \).

Hence, \( r_n \) is of degree \( 2n - 2 \) and its leading coefficient is \( 2^{n-1} \text{Cat}_n \). Still by the induction hypothesis:

- For the first term of (33):
  - If \( i, j, k \geq 2 \), then \( w^2 (w - 1) r_i r_j r_k \) is a multiple of \( w^{n+2} \).
  - If only one of \( i, j, k \) is equal to 1, then \( w^2 (w - 1) r_i r_j r_k \) is a multiple of \( w^{n+1} \).
  - If two of \( i, j, k \) are equal to 1, then the other one is equal to \( n - 2 \geq 2 \) and \( w^2 (w - 1) r_i r_j r_k \) is a multiple of \( w^n \).

Hence, this first term is a multiple of \( w^n \) and its contribution to the coefficient of \( w^n \) is
\[
-3(-1)^{n-2} (n - 2).
\]

- For the second term of (33):
  - If \( i, j \geq 2 \), then \( w^2 r_i r_j \) is a multiple of \( w^{n+1} \).
  - If one of \( i \) or \( j \) is equal to 1, then the second one is \( n - 2 \geq 2 \) and \( w^2 r_i r_j \) is a multiple of \( w^n \).

Hence, this second term is a multiple of \( w^n \) and its contribution to the coefficient of \( w^n \) is
\[
2(-1)^{n-2} (n - 2).
\]

- For the third term of (33):
  - If \( i, j \geq 2 \), then \( w^2 r_i r_j \) is a multiple of \( w^{n+1} \).
  - If one of \( i \) or \( j \) is equal to 1, then the second one is \( n - 1 \geq 2 \) and \( w(2w - 2) r_i r_j \) is a multiple of \( w^n \).
  - If \( n \) is even, then any coefficient of \( r_n \) is even.

Hence, this third term is a multiple of \( w^n \) and its contribution to the coefficient of \( w^n \) is
\[
-2 \times 2(-1)^{n-1} (n - 1).
\]

- The last term of (33) is a multiple of \( w^n \) and its contribution to the coefficient of \( w^n \) is
\[
2(-1)^{n-1} (n - 1).
\]
Finally, $r_n$ is a multiple of $w^n$ and the coefficient of $w^n$ in $r_n$ is

$$-3(-1)^n(n - 2) + 2(-1)^n(n - 2) + 4(-1)^n(n - 1) - 2(-1)^n(n - 1) = (-1)^n n.$$

Let us assume that $n$ is even. Then, in $\mathbb{Z}/2\mathbb{Z}[w]$:

$$r_n \equiv w^2(w - 1) \sum_{i+j+k=n} r_ir_jr_k + w^2 \sum_{i+j=n-1} r_ir_j + 0[2].$$

As $n$ is even, in the first term, one or three of $i, j, k$ are even, so $r_ir_jr_k \equiv 0[2]$; in the second term, one of $i, j$ is even, so $r_ir_j \equiv 0[2]$. Finally, $r_n \equiv 0[2]$. □

3. Reminders on operads and colored operads in the species formalism

Colored operads are natural tools to be used in the description of algebraic structures on graded objects. We give a description of those in the colored species formalism, mainly following the presentation of [7]. We also give a reminder of the more familiar monochromatic case, i.e. ordinary operads, and we describe a pair $(\mathcal{F}, \mathcal{U})$ of adjoint functors from colored operads to monochromatic operads and vice-versa, along the lines of [2].

3.1. Colored species. Let $\mathcal{C}$ be a bicomplete symmetric monoidal category, i.e. with small limits and colimits, which in particular implies the existence of products and coproducts indexed by an arbitrary set. For example the category of sets (the product given by cartesian product and the coproduct given by disjoint union), or the category of vector spaces over a field $k$ (the product given by cartesian product and the coproduct being given by direct sum) [15, 1]. The unit for the monoidal product will be denoted by $1$, or $1_{\mathcal{C}}$ if the mention of the category must be specified.

Monoidal categories of $\Omega$-graded objects, where $\Omega$ is a semigroup, have been considered in [2]. The symmetric monoidal structure is given by the Cauchy product, which uses the semigroup structure of $\Omega$ in an essential way. In absence of such a structure on our set $\Omega$, we must go further and consider multiple gradings. Let $\mathcal{F}_\Omega$ be the category of $\Omega$-colored finite sets defined as follows:

- objects are triples $(A, \alpha, \omega)$ where $A$ is a finite set, $\omega \in \Omega$ (the output color) and $\alpha : A \rightarrow \Omega$ is a list of elements of $\Omega$ indexed by $A$ (the input colors).
- morphisms are given by bijective maps from $A$ onto $B$ together with re-indexing of colors: a morphism

$$\varphi : (A, \alpha, \omega) \longrightarrow (B, \beta, \zeta)$$

is given by an underlying bijective map $\overline{\varphi} : A \rightarrow B$ under the two conditions that $\omega = \zeta$ and $\alpha = \beta \circ \varphi$, otherwise there is no morphism from $(A, \alpha, \omega)$ to $(B, \beta, \zeta)$.

Definition 3.1. An $\Omega$-colored species $\mathcal{P}$ in the bicomplete monoidal category $\mathcal{C}$ is a contravariant functor $(A, \alpha, \omega) \mapsto \mathcal{P}_{A, \alpha, \omega}$ from $\mathcal{F}_\Omega$ to $\mathcal{C}$. The $\Omega$-colored species is positive if moreover $\mathcal{P}_{\emptyset, \omega, \omega} = 0_{\mathcal{C}}$ for any $\omega \in \Omega$, where $0_{\mathcal{C}}$ is the initial object.

This definition is borrowed from [7, Definition 2.2] which provides a slightly more general framework: $\Omega$-colored species correspond to $(\Omega, \Omega)$-collections therein. This can be straightforwardly extended to $\Omega$-colored bi-species, where several output colors are also allowed, to treat the case of colored ProPs and properads, but we shall not pursue this line of thought here.
3.2. **A brief summary of the monochromatic case.** The category \( \mathcal{F}_\Omega \) boils down to the category \( \mathcal{F} \) of finite sets with bijections when the set \( \Omega \) of colors is reduced to one element. We recover then the usual notion of (contravariant) species [13, 3, 17]. A \( \mathcal{C} \)-species is a contravariant functor from \( \mathcal{F} \) into \( \mathcal{C} \), where \( \mathcal{F} \) is the category of finite sets with bijections as morphisms. We stick to positive species, i.e. species \( \mathcal{P} \) such that \( \mathcal{P}_0 = 0_C \), where \( 0_C \) is the initial object of the monoidal category \( \mathcal{C} \) [17]. We adopt M. Mendez’ definition of an operad in the species formalism:

**Definition 3.2.** [17, Definition 3.1] An operad is a monoid in the category of positive species.

Hence the operads considered here have no nullary operations. To be concrete, it is a positive species \( \mathcal{P} \) together with partial compositions

\[
\circ_b : \mathcal{P}_B \otimes \mathcal{P}_C \longrightarrow \mathcal{P}_{B \uplus_b C}
\]

for any \( b \in B \), where \( B \uplus_b C \) stands for \( (B \setminus \{b\}) \sqcup C \), subject to both sequential and parallel associativity axioms, which are stated as follows: for any finite sets \( B, C, D \), for any \( \alpha \in \mathcal{P}_B \), \( \beta \in \mathcal{P}_C \) and \( \beta' \in \mathcal{P}_D \) we have

\[
\begin{align*}
\{ \alpha \circ_b (\beta \circ_c \gamma) & = (\alpha \circ_b \beta) \circ_c \gamma, \\
(\alpha \circ_b \beta) \circ_{b'} \beta' & = (\alpha \circ_{b'} \beta') \circ_b \beta.
\end{align*}
\]

3.3. **Colored operads.** In a colored operad, a partial composition is possible if and only if the output color of the second argument matches the color of the chosen input of the first. This is formalized as follows:

**Definition 3.3.** The substitution product of two positive \( \Omega \)-colored species is defined by

\[
(34) \quad (\mathcal{P} \boxdot \mathcal{Q})_{A, \alpha, \omega} := \bigoplus_{\pi \text{ set partition of } A} \prod_{\gamma \pi \rightarrow \Omega} \mathcal{P}_{\pi \gamma, \omega} \otimes \bigotimes_{B \in \pi} \mathcal{Q}_{B \gamma, \omega}(B).
\]

The substitution product \( \boxdot \) is also defined on morphisms and is associative, making the category of positive \( \Omega \)-colored species a (non-symmetric) monoidal category. The unit is the colored species \( 1 \) defined by \( 1_{A, \alpha, \omega} = 1_C \) if \( |A| = 1 \) and \( \alpha = \omega \), and \( 1_{A, \alpha, \omega} = 0 \) otherwise. It can be written as

\[
1 = \prod_{\omega \in \Omega} 1^\omega
\]

where \( 1^\omega \) is the colored species defined by \( 1^\omega_{A, \alpha, \zeta} = 1_C \) if \( |A| = 1 \) and \( \alpha = \zeta = \omega \), and \( 1^\omega_{A, \alpha, \zeta} = 0 \) otherwise. The colored species \( 1^\omega \) is sometimes slightly abusively called *unit of color* \( \omega \).

**Definition 3.4.** A **colored operad** is a monoid in the monoidal category of positive \( \Omega \)-colored species endowed with the substitution product.

Concretely, the global multiplication \( \gamma : \mathcal{P} \boxdot \mathcal{P} \rightarrow \mathcal{P} \) is declined into functorial partial compositions

\[
(36) \quad \circ_a : \mathcal{P}_{A, \alpha, \omega} \otimes \mathcal{P}_{B \gamma, \zeta} \longrightarrow \begin{cases} 
\mathcal{P}_{A \uplus a, B, \alpha, \omega, \gamma, \zeta} & \text{if } \zeta = \alpha(a), \\
0 & \text{otherwise}.
\end{cases}
\]

subject to parallel and sequential associativity axioms, and there is a unit \( e : 1 \rightarrow \mathcal{P} \). Informally, the partial composition \( \circ_a \) is nontrivial if and only if the output color of the second term matches the input color of the first term corresponding to \( a \in A \), otherwise \( \circ_a \) takes values in the terminal object \( 0_C \).
For any set map \( \kappa : \Omega \to \Omega' \), the color change functor from \( \Omega' \)-colored species to \( \Omega \)-colored species is defined by

\[
(\kappa^* \mathcal{P})_{A,\underline{\alpha},\omega} := \mathcal{P}_{A,\kappa \circ \underline{\alpha},\kappa(\omega)}
\]

for any \((A, \underline{\alpha}, \omega) \in \mathcal{F}_\Omega \). It respects both monoidal products \( \boxtimes \), hence restricts from \( \Omega' \)-colored operads to \( \Omega \)-colored operads. In particular, the case when \( \Omega' = \{\ast\} \) contains a unique element shows that any ordinary (monochromatic) operad \( Q \) can be promoted to an \( \Omega \)-colored operad \( \mathcal{U}_\Omega Q := \kappa^* Q \), with \( \kappa : \Omega \to \{\ast\} \).

This functor \( \mathcal{U} : \Omega \to \mathcal{Q}^\Omega \) is right-adjoint to the completed forgetful functor \( \mathcal{F} \) from \( \Omega \)-colored operads to ordinary operads, defined by

\[
(\mathcal{FP})_{A} := \prod_{(\underline{\alpha},\omega) \in \Omega^A \times \Omega} \mathcal{P}_{A,\underline{\alpha},\omega}.
\]

3.4. Categories of graded objects. We keep the notations of the previous paragraph. The category \( \mathcal{C}_\Omega \) of \( \Omega \)-graded objects [2, Paragraph 2.2] is the category of collections \((V_\omega)_{\omega \in \Omega}\) of objects of \( \mathcal{C} \). A \( \mathcal{C}_\Omega \)-morphism

\[
\varphi : (V_\omega) \to (W_\omega)
\]

is a collection \((\varphi_\omega)_{\omega \in \Omega}\) of \( \mathcal{C} \)-morphisms \( \varphi_\omega : V_\omega \to W_\omega \). This is not a monoidal category: indeed, the tensor product of two \( \Omega \)-graded objects is a collection indexed by \( \Omega \times \Omega \).

Remark 3.5. In the case when \( \Omega \) is a semigroup, categories of \( \Omega \)-graded objects can be given a monoidal structure by means of the Cauchy product [2, Paragraph 2.2]. We do not have this tool at our disposal here.

A well-known example of \( \Omega \)-colored operad (in a bicomplete category \( \mathcal{C} \) with internal Hom, i.e. such that \( \text{Hom}(V,W) \) is an object of \( \mathcal{C} \) for any pair \((V,W)\) of objects) is given by \( \text{End}(V) \) where \( V = (V_\omega)_{\omega \in \Omega} \) is an \( \Omega \)-graded object:

\[
\text{End}(V)_{A,\underline{\alpha},\omega} := \text{Hom}_\mathcal{C}
\left( \bigotimes_{a \in A} V_\alpha(a), V_\omega \right).
\]

Details are standard and left to the reader. An algebra over an \( \Omega \)-colored operad \( \mathcal{P} \) is an \( \Omega \)-graded object \( V \) together with a morphism of colored operads \( \Phi : \mathcal{P} \to \text{End}(V) \).

Definition 3.6. [2, Paragraph 2.2] An \( \Omega \)-graded object \( V = (V_\omega)_{\omega \in \Omega} \) is uniform if all homogeneous components are identical, i.e. if there is an object \( V \) of \( \mathcal{C} \) such that \( V_\omega = V \) for any \( \omega \in \Omega \). We write \( V = \mathcal{U}(V) \) in this case. This defines a functor \( \mathcal{U} : \mathcal{C} \to \mathcal{C}_\Omega \), which has a right adjoint, the forgetful functor \( \mathcal{F} : \mathcal{C}_\Omega \to \mathcal{C} \) defined by

\[
\mathcal{F}(V) := \bigsqcup_{\omega \in \Omega} V_\omega,
\]

which consists in forgetting the \( \Omega \)-grading [2, Paragraph 2.4]. It has also a left adjoint, the completed forgetful functor \( \overline{\mathcal{F}} : \mathcal{C}_\Omega \to \mathcal{C} \) defined by

\[
\overline{\mathcal{F}}(V) := \bigsqcup_{\omega \in \Omega} V_\omega,
\]

which consists taking the completion with respect to the \( \Omega \)-grading and then forgetting it.
4. Two-parameter $\Omega$-pre-Lie algebras

The pre-Lie operad is no longer a set operad, hence new phenomena arise when seeking a compatible structure on the parameter set $\Omega$. Indeed, four different associated set operads are involved. The first one is the well-known associative operad. The second one is the operad governing rings with the twist-associativity condition $x(yz) = (yx)z$, also known as Thedy rings [20]. The third one is the operad governing rings with both NAP relation $x(yz) = y(xz)$ and NAP′ relation $(xy)z = (yx)z$. The fourth one is the operad governing rings with all previous relations at once, this is the well-known Perm operad [5, 6]. After explaining this phenomenon in some detail, we give an explicit description of the twist-associative operad in terms of ordered pairs of distinct elements, and an explicit description of the NAPNAP′ operad in terms of corollas, in the same spirit F. Chapoton and M. Livernet proved that the pre-Lie operad is given by labeled rooted trees [6].

4.1. Four possibilities. Let $A$ be a vector space and let $\Omega$ be a set with a binary operation $\triangleright$. Suppose that $A \otimes k\Omega$ is endowed with an $\Omega$-graded pre-Lie product:

$$
(\otimes \alpha) \triangleright (\otimes \beta) := \triangleright_{\alpha,\beta} y \otimes (\alpha \triangleright \beta).
$$

The pre-Lie axiom

$$(\otimes \alpha) \triangleright ((\otimes \beta) \otimes (\otimes \gamma)) - ((\otimes \alpha) \triangleright (\otimes \beta)) \otimes (\otimes \gamma) = (\otimes \alpha) \triangleright ((\otimes \beta) \triangleright (\otimes \gamma)) - ((\otimes \beta) \triangleright (\otimes \alpha)) \triangleright (\otimes \gamma)
$$

together with the $\Omega$-grading are equivalent to

$$
x \triangleright_{\alpha,\beta,\gamma} (y \triangleright_{\beta,\gamma} z) \otimes (\alpha \triangleright (\beta \triangleright \gamma)) - (x \triangleright_{\alpha,\beta} y) \triangleright_{\alpha,\beta,\gamma} z \otimes ((\alpha \triangleright \beta) \triangleright \gamma)
$$

$$
= y \triangleright_{\beta,\alpha,\gamma} (x \triangleright_{\alpha,\gamma} z) \otimes (\beta \triangleright (\alpha \triangleright \gamma)) - (y \triangleright_{\beta,\alpha} x) \triangleright_{\beta,\alpha,\gamma} y \otimes ((\beta \triangleright \alpha) \triangleright \gamma).
$$

Eq. (41) induces four possible different cases.

**Case 1:** let $\alpha \triangleright (\beta \triangleright \gamma) = (\alpha \triangleright \beta) \triangleright \gamma$ for $\alpha, \beta, \gamma \in \Omega$. Thus $\Omega$ is a semigroup. Then

$$
x \triangleright_{\alpha,\beta,\gamma} (y \triangleright_{\beta,\gamma} z) = (x \triangleright_{\alpha,\beta} y) \triangleright_{\alpha,\beta,\gamma} z,
$$

for $\alpha, \beta, \gamma \in \Omega$

and we recover the notion of family associative algebra.

**Case 2:** let

$$
\alpha \triangleright (\beta \triangleright \gamma) = (\beta \triangleright \alpha) \triangleright \gamma
$$

for $\alpha, \beta, \gamma \in \Omega$. Then $\Omega$ is a kind of “twisted associative semigroup”, a notion which has received little attention in the literature (see however [20] and [21]). We have then

$$
x \triangleright_{\alpha,\beta,\gamma} (y \triangleright_{\beta,\gamma} z) = -(y \triangleright_{\beta,\alpha} x) \triangleright_{\beta,\alpha,\gamma} z
$$

and we recover a notion of “family twisted associative algebra” modulo a minus sign.

We now give examples of twisted semigroups, i.e. sets endowed with a binary product $\triangleright$ verifying Eq. (42): for any set $D$ we consider the set $\mathbb{N}^D$ of maps form $D$ into the set $\mathbb{N} = \{0, 1, 2, 3, \ldots\}$ of nonnegative integers. Such a map will be denoted by $\alpha = (\alpha_d)_{d \in D}$. For any $d \in D$, we denote by $\delta_d$ the map such that $\delta_d(d) = 1$ and $\delta_d(e) = 0$ for any $e \in D \setminus \{d\}$. Any element $\alpha \in \mathbb{N}^D$ will be represented by the monomial $X^\alpha$ in $d$ variables defined by

$$
X^\alpha := \prod_{d \in D} X_d^\alpha_d.
$$
Now consider the set
\[ T_D := D \times D \times \mathbb{N}^D. \]
A generic element of \( T_D \) will be denoted by \( dd'X^\alpha \) with \( d, d' \in D \) and \( \alpha \in \mathbb{N}^D \). Let us now define the product by
\[ dd'X^\alpha \triangleright ee'X^\beta := d' e'X^{\alpha+\beta+\delta_x+\delta_y}. \]
The product verifies Equation (42). Indeed, an easy computation yields
\[
dd'X^\alpha \triangleright (ee'X^\beta \triangleright f f'X^\gamma) = (ee'X^\beta \triangleright dd'X^\alpha) \triangleright f f'X^\gamma = d' f'X^{\alpha+\beta+\gamma+\delta_x+\delta_y+\delta_x+\delta_y}.
\]
we prove in Paragraph 4.2 that \( T_D \) is the free twisted semigroup generated by \( D \), and we give an explicit description of the twist-associative set operad.

**Case 3:** let
\[
\begin{align*}
\alpha \bullet (\beta \bullet \gamma) &= \beta \bullet (\alpha \bullet \gamma), \\
(\alpha \bullet \beta) \bullet \gamma &= (\beta \bullet \alpha) \bullet \gamma.
\end{align*}
\]
The first relation is the NAP condition. We call NAP’ the second condition, and we call \( \Omega \) a NAPNAP’ set. Then
\[
\left\{ \begin{array}{l}
x \triangleright_{\alpha,\beta} (y \triangleright_{\beta,\gamma} z) = y \triangleright_{\beta,\gamma} (x \triangleright_{\alpha,\gamma} z), \\
(x \triangleright_{\alpha,\beta} y) \triangleright_{\alpha,\gamma} z = (y \triangleright_{\beta,\alpha} x) \triangleright_{\beta,\alpha,\gamma} z.
\end{array} \right.
\]
We obtain what we shall call family NAPNAP’ algebras.

We give an example of set endowed with a binary product \( \triangleright \) verifying Eq. (44), namely the set \( \mathbb{N} \) of multisets of positive integers (including the empty multiset \( \phi \)). Let \( n := \{ n_1, \ldots, n_k \} \), \( p = \{ p_1, \ldots, p_\ell \} \) and \( q = \{ q_1, \ldots, q_m \} \) be three elements of \( \mathbb{N} \). Define the product \( \triangleright \) by
\[
n \triangleright p := \{ n_1 + \cdots + n_k + 1, p_1, \ldots, p_\ell \}.
\]
Then,
\[
\begin{align*}
n \triangleright (p \triangleright q) &= p \triangleright (n \triangleright q) = \{ n_1 + \cdots + n_k + 1, p_1 + \cdots + P_\ell + 1, q_1, \ldots, q_m \}, \\
(n \triangleright p) \triangleright q &= (p \triangleright n) \triangleright q = \{ n_1 + \cdots + n_k + p_1 + \cdots + p_\ell + 2, q_1, \ldots, q_m \}.
\end{align*}
\]
We’ll prove in Paragraph 4.3 that this is the free NAPNAP’ set generated by the element \( \phi \), by giving an explicit description of the NAPNAP’ operad.

**Case 4:** for any \( \alpha, \beta, \gamma \in \Omega \),
\[
\alpha \triangleright (\beta \triangleright \gamma) = (\alpha \triangleright \beta) \triangleright \gamma = \beta \triangleright (\alpha \triangleright \gamma) = (\beta \triangleright \alpha) \triangleright \gamma,
\]
i.e. \( \Omega \) is a set-theoretical Perm algebra. Then for any \( x, y, z \in A \),
\[
x \triangleright_{\alpha,\beta}(y \triangleright_{\beta,\gamma} z) - (x \triangleright_{\alpha,\beta} y) \triangleright_{\alpha,\beta,\gamma} z = y \triangleright_{\beta,\alpha,\gamma} (x \triangleright_{\alpha,\gamma} z) - (y \triangleright_{\beta,\alpha} x) \triangleright_{\beta,\alpha,\gamma} z.
\]
This relation is very similar to the pre-Lie one, and deserves the name "pre-Lie family". We address this last case in Paragraph 4.4.
4.2. The twist-associative operad TAs.

**Definition 4.1.** Let \( \mathcal{P} \) be the set species of non-diagonal ordered pairs, defined by

\[
\mathcal{P}_{|_1} = \{1\}, \\
\mathcal{P}_A = \{(a', a'') \in A \times A, a' \neq a''\}.
\]

for any finite set \( A \) of cardinal \( \geq 2 \). For any bijection \( \phi : A \to B \) where \( B \) is a finite set of the same cardinality than \( A \), the relabeling isomorphism \( \mathcal{P}_\phi : \mathcal{P}_B \to \mathcal{P}_A \) is defined by

\[
\mathcal{P}_\phi(b', b'') = \left(\phi^{-1}(b'), \phi^{-1}(b'')\right).
\]

**Definition 4.2.** Let \( A \) and \( B \) be two finite sets. Define partial compositions

\[\circ_a : \mathcal{P}_A \otimes \mathcal{P}_B \to \mathcal{P}_{A \cup B \setminus \{a\}, \text{ for } a \in A.}\]

as follows: for any ordered pair \((a', a'') \in \mathcal{P}_A\) and \((b', b'') \in \mathcal{P}_B\), we set

\[
(a', a'') \circ_a (b', b'') = \begin{cases} 
(b'', a''), & \text{if } a = a' \\
(a', b''), & \text{if } a = a'' \\
(a', a''), & \text{if } a \notin \{a', a''\}.
\end{cases}
\]

Partial compositions are extended to singletons by setting 1 as the unit.

**Proposition 4.3.** The species \( \mathcal{P} \) together with the partial compositions \( \circ_a \) defined by Eq. (45) is an operad.

**Proof.** Let \( A, B, C \) be three sets of cardinal \( \geq 2 \), and let \( x = (a', a'') \in A \times A, y = (b', b'') \in B \times B, z = (c', c'') \in C \times C \). When we prove sequential associativity, there are nine cases to consider.

</tbody>
</table>

Extending to the case where \( A, B \) or \( C \) has only one element is straightforward and left to the reader. \( \square \)

**Proposition 4.4.** Let \( A = \{1, 2\}, \) let \( \mu = (1, 2) \in \mathcal{P}_A, \) and let \( \overline{\mu} = (2, 1) \) be the other element of \( \mathcal{P}_A \) obtained by permutation. The twist-associativity relation

\[
x \circ_\pi y = \mu \circ_2 \mu - \mu \circ_1 \overline{\mu} = 0
\]

holds in the operad \( \mathcal{P}. \)

**Proof.** Denoting by \( \{a, b\} \) another copy of \( A \) (identifying \( a \) with \( 1 \) and \( b \) with \( 2 \)), both three-element sets \( A \uplus_2 A \) and \( A \uplus_1 A \) must be identified by means of the bijection

\[
\begin{pmatrix}
1 & a \\
\hline
a & b \\
\hline
2 & \overline{a}
\end{pmatrix}
\]

in order to make Equation (46) consistent. We get then

\[
\mu \circ_2 \mu = (1, 2) \circ_2 (a, b) = (1, b) \in \mathcal{P}_{\{1,a,b\}}, \quad \mu \circ_1 \overline{\mu} = (1, 2) \circ_1 (b, a) = (a, 2) \in \mathcal{P}_{\{a,b,2\}},
\]

hence \( \mu \circ_2 \mu = \mu \circ_1 \overline{\mu} \) modulo the identification above. \( \square \)

For later use, for any \( A, B \) finite sets we define the product \( \triangleright: \mathcal{P}_A \otimes \mathcal{P}_B \to \mathcal{P}_{A \sqcup B} \) by

\[
\alpha \triangleright \beta := (\mu \circ_1 \alpha) \circ_2 \beta.
\]

An easy computation yields:

\[
\begin{align*}
1 \triangleright 1 & = \mu, \\
1 \triangleright (x, y) & = (\ast, y), \\
(x, y) \triangleright 1 & = (y, \ast), \\
(x, y) \triangleright (z, t) & = (y, t)
\end{align*}
\]
for any \( x, y \in A \) and \( z, t \in B \) with \( x \neq y \) and \( z \neq t \). It is easily checked that the product verifies the twist-associative identity

\[
\alpha \triangleright (\beta \triangleright \gamma) = (\beta \triangleright \alpha) \triangleright \gamma
\]

for any finite sets \( A, B, C \) and for any \( \alpha \in \mathcal{P}_A, \beta \in \mathcal{P}_B \) and \( \gamma \in \mathcal{P}_C \).

**Theorem 4.5.** The operad \( \mathcal{P} \) of non-diagonal ordered pairs is isomorphic to the twist-associative operad \( \mathcal{T} := \mathcal{M}/\langle r \rangle \).

**Proof.** We still adopt the notations in the proof of Proposition 4.4. The twist-associative operad is defined as the quotient of the magmatic operad \( \mathcal{M} \) (the free operad generated by a single binary operation \( \triangleright \)) by the ideal \( \langle r \rangle \) generated by the twist-associative relation \( r = \nu \circ_2 \nu - \nu \circ_1 \nu \). Let \( A, B, C \) be three finite sets. Defining \( \tilde{\nu} \) as the image of \( \nu \) in the quotient, we have

\[
\alpha \triangleright (\beta \triangleright \gamma) = (\beta \triangleright \alpha) \triangleright \gamma
\]

for any \( \alpha \in \mathcal{T}_A, \beta \in \mathcal{T}_B \) and \( \gamma \in \mathcal{T}_C \), where \( \triangleright \) is defined by

\[
\alpha \triangleright \beta := (\tilde{\nu} \circ_1 \alpha) \circ_2 \beta.
\]

As the ordered pair \( \mu = (1, 2) \) verifies the twist-associative relation (46), there is a unique surjective operad morphism \( \Phi : \mathcal{T} \to \mathcal{P} \) such that \( \Phi(\tilde{\nu}) = \mu \). It obviously verifies

\[
\Phi(\alpha \triangleright \beta) = \Phi(\alpha) \triangleright \Phi(\beta)
\]

for any \( \alpha \in \mathcal{T}_A \) and \( \beta \in \mathcal{T}_B \). Let us prove that \( \Phi \) is bijective. Define \( \Psi_A : \mathcal{P}_A \to \mathcal{T}_A \) by induction on the arity \( n = |A| \geq 2 \). For \( n = 1 \) we set \( \Psi(1) = 1 \), and for \( n = 2 \) it amounts to \( \Psi(\mu) = \tilde{\nu} \). Suppose that the inverse \( \Psi \) of \( \Phi \) is well-defined (and hence bijective) up to arity \( n \), and let \( A \) be of cardinality \( n + 1 \). From (48), any \( (x, y) \in \mathcal{P}_A \) can be written \( (x, y) = 1 \triangleright (x', y) \), where \( 1 \in \mathcal{P}_{\{x\}} \) and \( (x', y) \in \mathcal{P}_{A \setminus \{x\}} \). Hence we necessarily have

\[
\Psi(x, y) = 1 \triangleright \Psi(x', y).
\]

It is well defined because it does not depend on the choice of \( x' \). Indeed, if another choice \( x'' \) is possible, then

\[
(x, y) = 1 \triangleright (x'', y) = 1 \triangleright (1 \triangleright (x', y)),
\]

hence

\[
1 \triangleright \Psi(x'', y) = 1 \triangleright (1 \triangleright \Psi(x', y)), \quad (x', y) \in A \setminus \{x, x''\}
\]

\[
= 1 \triangleright (1 \triangleright \Psi(x', y)), \quad (x'', y) \in A \setminus \{x, x'\} \quad \text{(by induction hypothesis)},
\]

\[
= 1 \triangleright \Psi(x', y) \quad \text{(again by induction hypothesis)}.
\]

We have

\[
\Phi(\Psi(x, y)) = 1 \triangleright \Phi(\Psi(x', y)) = 1 \triangleright (x', y) = (x, y)
\]

by induction hypothesis, hence \( \Phi_A \Psi_A = 1_{\mathcal{P}_A} \). Furthermore, for any partition \( A = B \sqcup C \) and for any \( \beta \in \mathcal{P}_B, \gamma \in \mathcal{P}_C \) we have

\[
\Psi(\beta \triangleright \gamma) = \Psi(\beta) \triangleright \Psi(\gamma).
\]

This is easily proven by induction on the cardinality of \( B \), the case \( |B| = 1 \) being equivalent to the definition of \( \Psi \): if \( |B| \geq 2 \) we write \( \beta = 1 \triangleright \beta' \) and then

\[
\Psi(\beta \triangleright \gamma) = \Psi((1 \triangleright \beta') \triangleright \gamma)
\]

\[
= \Psi(\beta' \triangleright (1 \triangleright \gamma)) \quad \text{(by (51))}
\]

\[
= \Psi(\beta') \triangleright \Psi(1 \triangleright \gamma) \quad \text{(by induction on \( |B| \))}
\]
Now any $\alpha \in T_A$ can be written $\beta \triangleright \gamma$ with $\beta \in T_B$, $\gamma \in T_C$, where $B$ and $C$ are two finite sets of cardinality $\leq n$ such that $A = B \sqcup C$. We have then

$$\Psi(\Phi(\alpha)) = \Psi(\Phi(\beta \triangleright \gamma)) = \Psi(\Phi(\gamma)) \ (\text{by } (52))$$

again by induction hypothesis, hence $\Psi_A \Phi_A = \text{Id}_{T_A}$. This ends up the proof of Theorem 4.5. \square

Let us remark that, forgetting the labels and putting instead a decoration by a given set $D$, we recover the description of the free twisted associative semigroup generated by $D$ given in Paragraph 4.1.

4.3. The operad NAPNAP’ of corollas.

**Definition 4.6.** A **corolla structure** $\beta$ on a finite set $B$ is a quasi-order admitting one unique minimum $r$, such that any element different from $r$ is a maximum.

The unique minimum $r$ is the root of the corolla. Any $b \neq r$ verifies $r \leq b$ but never $b \leq r$. The non-root elements are partitioned into branches $B_1, \ldots, B_p$, which are the equivalence classes (excluding the one of the root) under the relation $\sim$ defined by $b \sim b'$ if and only if $b \leq b'$ and $b' \leq b$. We shall write

$$\beta = [B_1, \ldots, B_p].$$

For example, on the finite set $B : \{a, b, c, d, e, f, g\}$, the notation $\beta = \begin{bmatrix} \{b, c\}, \{d\}, \{e, f, g\} \end{bmatrix}$ stands for the corolla

$$\beta = \begin{array}{c}
bc \\
\downarrow d \\
\downarrow f g \\
\end{array}$$

Let $\mathbb{K}_B$ be the set of corolla structures on $B$. This forms a set species: any bijection $\varphi : B \to C$ induces a bijection $\mathbb{K}_{\varphi} : \mathbb{K}_C \to \mathbb{K}_B$ by relabeling.

Now let us define the operad structure. Let $B, C$ be two finite sets, let $b \in B$, let $\beta \in \mathbb{K}_B$ and $\gamma \in \mathbb{K}_C$. Let $r$ be the root of the corolla $\gamma$. The partial composition $\beta \circ_b \gamma : \mathbb{K}_B \times \mathbb{K}_C \to \mathbb{K}_{B \sqcup_b C}$ is defined as follows:

- if $b$ is the root of $\beta$, then $\beta \circ_b \gamma$ is the corolla on $B \sqcup_b C$ obtained by choosing $r$ as the root, and by keeping all branches in $B \sqcup_b C \setminus \{r\}$. In particular, elements in $B \setminus \{b\}$ and elements in $C \setminus \{r\}$ belong to different branches, and thus are incomparable.
- if $b$ is not the root of $\beta$, then $\beta \circ_b \gamma$ is the corolla on $B \sqcup_b C$ obtained by replacing $b$ by the whole $C$ in the branch of $b$.

Let us give an example for better understanding.
We leave it to the reader to show that \( K \) endowed with the partial compositions defined above is an operad, i.e. prove both sequential and parallel associativity axioms. Now define the product \( \triangleright \) on \( K \) by

\[
\beta \triangleright \gamma := \left( \begin{array}{c}
1 \\
2 \\
3 \\
\end{array} \right) \circ_1 \beta \circ_2 \gamma.
\]

**Proposition 4.7.** The product \( \triangleright \) verifies for any \( \alpha, \beta, \gamma \in K \):

(a) \( \alpha \triangleright (\beta \triangleright \gamma) = \beta \triangleright (\alpha \triangleright \gamma) \),

(b) \( (\alpha \triangleright \beta) \triangleright \gamma = (\beta \triangleright \alpha) \triangleright \gamma \).

**Proof.** Both sides of Equation (a) are equal to

\[
\left( \begin{array}{c}
1 \\
2 \\
3 \\
\end{array} \right) \circ_1 \alpha \circ_2 \beta \circ_3 \gamma,
\]

and both sides of Equation (b) are equal to

\[
\left( \begin{array}{c}
1 \\
2 \\
3 \\
\end{array} \right) \circ_1 \alpha \circ_2 \beta \circ_3 \gamma.
\]

Details are left to the reader. \( \Box \)

**Theorem 4.8.** The operad \( K \) of corollas is the NAPNAP' operad.

**Proof.** The NAPNAP' operad is defined as the quotient of the magmatic operad \( M \) by the NAP and NAP' relations, namely

\[
\text{NAPNAP'} := M/\langle \mu \circ_2 \mu - \tau_{12} (\mu \circ_2 \mu), \ \mu \circ_1 \mu - \tau_{12} (\mu \circ_1 \mu) \rangle.
\]

Defining \( \overline{\mu} \) as the image of \( \mu \) in the quotient, we further introduce the product \( \triangleright \) on the NAPNAP' operad itself, defined by

\[
\alpha \triangleright \beta := (\overline{\mu} \circ_1 \alpha) \circ_2 \beta.
\]

The NAP and NAP' relations for \( \overline{\mu} \) yield analogous relations for \( \triangleright \), namely

(a) \( \alpha \triangleright (\beta \triangleright \gamma) = \beta \triangleright (\alpha \triangleright \gamma) \),

(b) \( (\alpha \triangleright \beta) \triangleright \gamma = (\beta \triangleright \alpha) \triangleright \gamma \).

The corolla \( \begin{array}{c}
1 \\
2 \\
\end{array} \) respects both NAP and NAP' relations, namely

\[
\begin{array}{cc}
1 & 2 \\
\circ_1 & \circ_2
\end{array} = \tau_{12} \left( \begin{array}{cc}
1 & 2 \\
\circ_1 & \circ_2
\end{array} \right) = \begin{array}{cc}
1 & 2 \\
\circ_1 & \circ_2
\end{array}.
\]

and

\[
\begin{array}{cc}
1 & 2 \\
\circ_1 & \circ_2
\end{array} = \tau_{12} \left( \begin{array}{cc}
1 & 2 \\
\circ_1 & \circ_2
\end{array} \right) = \begin{array}{cc}
1 & 2 \\
\circ_1 & \circ_2
\end{array}.
\]

Hence the operad morphism \( \overline{\Phi} \) from \( M \) onto \( K \) uniquely defined by \( \overline{\Phi}(\mu) = \begin{array}{c}
1 \\
2 \\
\end{array} \) vanishes on the ideal generated by the NAP and NAP' relations, giving rise to the unique surjective operad morphism

\[
\Phi : \text{NAPNAP'} \longrightarrow K
\]

such that \( \Phi(\mu) = \begin{array}{c}
1 \\
2 \\
\end{array} \). It is obvious that \( \Phi \) changes product \( \triangleright \) into product \( \triangleright \). It remains to prove that \( \Phi \) is an isomorphism. We will prove the existence of an inverse \( \Psi : K_B \rightarrow \text{NAPNAP'}_B \) of \( \Phi : \text{NAPNAP'}_B \rightarrow K_B \) for any finite set \( B \) by induction on the cardinal of \( B \). The cases where \( B \) has one or two elements are trivial. Suppose the result to be true up to \( n \) elements, and let \( B \) be of
cardinal \( n + 1 \). For any corolla structure \( \beta \) on \( B \), there is \( r \in B \) and a partition \( B \setminus \{ r \} = B_1 \sqcup \cdots \sqcup B_p \) such that

\[
\beta = [B_1, \ldots, B_p].
\]

We now proceed by a secondary induction on \( p \). If \( p = 1 \), we have \( \beta = [B_1] \triangleright [r] \), where \( \beta \) is any corolla structure on \( B \setminus \{ r \} \), and where we identify the one-element set \( \{ r \} \) with the only corolla structure which exists on it. We set:

\[
\Psi(\beta') \triangleright 1,
\]

\( \Phi \Psi(\beta) = \Phi \Psi(\beta') \triangleright \Phi \Psi([r]) = \beta \) by induction hypothesis. For \( p \geq 2 \) we have

\[
\beta = [B_1, \ldots, B_p], \quad \beta_1 \triangleright [B_2, \ldots, B_p],
\]

where \( \beta_1 \) is any corolla structure on \( B_1 \). We can define by induction hypothesis:

\[
\Psi(\beta) := \Psi(\beta_1) \triangleright \Psi([B_2, \ldots, B_p]).
\]

We have again \( \Phi \Psi(\beta) = \beta \) for the same reasons. To make sure that \( \Psi(\beta) \) is well-defined, one has to prove that the result is invariant under permutation of the \( p \) branches. Invariance under permutation of the \( p - 1 \) last ones is obvious by secondary induction hypothesis. To get invariance under permutation of \( B_1 \) and \( B_2 \), define

\[
\Psi'(\beta) := \Psi(\beta_2) \triangleright \Psi([B_1, B_3, \ldots, B_p]),
\]

where \( \beta_2 \) is any corolla structure on \( B_2 \). We have then

\[
\Psi(\beta) = \Psi(\beta_1) \triangleright \Psi([B_2, \ldots, B_p]),
\]

\[
= \Psi(\beta_1) \triangleright (\Psi(\beta_2) \triangleright \Psi([B_3, \ldots, B_p])),
\]

\[
= (\Psi(\beta_1) \triangleright \Psi(\beta_2)) \triangleright \Psi([B_3, \ldots, B_p]),
\]

\[
= (\Psi(\beta_2) \triangleright \Psi(\beta_1)) \triangleright \Psi([B_3, \ldots, B_p]),
\]

\[
= \Psi(\beta_2) \triangleright (\Psi(\beta_1) \triangleright \Psi([B_3, \ldots, B_p])),
\]

\[
= \Psi(\beta_2) \triangleright \Psi([B_1, B_3, \ldots, B_p]),
\]

\[
= \Psi'(\beta).
\]

Finally we also have \( \Psi \Phi = \text{Id}_{\text{NAPNAP}} \). It is easily proven by induction on arity, using \( \Psi(\alpha \triangleright \beta) = \Psi(\alpha) \triangleright \Psi(\beta) \). This ends up the proof of Theorem 4.8. \( \square \)

4.4. Two-parameter \( \Omega \)-pre-Lie algebras and the Perm operad. Now we give the definition of two-parameter \( \Omega \)-pre-Lie algebras. This requires that the product \( \triangleright \) on \( \Omega \) fulfills the requirements of the fourth case of Paragraph 4.1.

**Definition 4.9.** Let \( \Omega \) be a set-theoretical perm algebra \([6, 5]\), i.e. a set with a product \( \triangleright \) such that

\[
\alpha \triangleright (\beta \triangleright \gamma) = (\alpha \triangleright \beta) \triangleright \gamma = \beta \triangleright (\alpha \triangleright \gamma) = (\beta \triangleright \alpha) \triangleright \gamma
\]

for any \( \alpha, \beta, \gamma \in \Omega \), i.e. we ask that the product \( \triangleright \) is both associative and NAP. A **two-parameter \( \Omega \)-pre-Lie algebra** is a family \((A, (\triangleright_{\alpha, \beta})_{\alpha, \beta \in \Omega})\) where \( A \) is a vector space and \( \triangleright_{\alpha, \beta} : A \otimes A \to A \), such that for any \( x, y, z \in A \) and \( \alpha, \beta \in \Omega \), satisfying

\[
x \triangleright_{\alpha, \beta} (y \triangleright_{\beta, \gamma} z) = (x \triangleright_{\alpha, \beta} y) \triangleright_{\alpha, \beta} \gamma\]

\[
\triangleright_{\beta, \alpha} \triangleright_{\alpha, \beta} \gamma \rightleftharpoons (x \triangleright_{\alpha, \gamma} z) \triangleright_{\beta, \alpha, \gamma} \rightleftharpoons (y \triangleright_{\beta, \alpha} x) \triangleright_{\beta, \alpha, \gamma} \rightleftharpoons z.
\]
The Perm operad governing relations (54) has been described in [5]. In the species formalism, \( \text{Perm}_A := A \) for any finite set \( A \), and the partial compositions are defined as follows: for any finite sets \( A, B, \) for any \( a, a' \in A \) and \( b' \in B \),

\[
a' \circ_a b' = \begin{cases} 
  b' & \text{if } a = a' \\
  a' & \text{if } a \neq a'.
\end{cases}
\]

Note that if \( (\Omega, \bullet) \) is a set-theoretical Perm algebra, then it is also a semigroup, a twisted associative semigroup, and a set-theoretical \( \text{NAPNAP}' \) algebra. Hence, we can consider the operad \( \text{As}_\Omega \) of family associative algebras on \( \Omega \) as in Case 1, \( \text{TAs}_\Omega \) of family twisted associative algebras on \( \Omega \) defined by (43) as in Case 2, \( \text{NAPNAP}'_\Omega \) of family \( \text{NAPNAP}' \) algebras on \( \Omega \) as in Case 3, and \( \text{PreLie}_\Omega \) of family pre-Lie algebras on \( \Omega \) as in Case 4. Then, in an immediate way:

**Proposition 4.10.** For any set-theoretical Perm algebra \( \Omega \), we have the two following diagrams.

\[
\begin{array}{c}
\text{As} \\
\text{TAs} \\
\text{NAPNAP}'
\end{array}
\xymatrix{
\ar[r] & \text{Perm} & \ar[l]_{} & \text{As}_\Omega \\
\ar[r] & \text{TAs}_\Omega & \ar[l]_{\text{PreLie}_\Omega} & \text{NAPNAP}'_\Omega
}
\]

The four operads in the first diagram are set operads, and all arrows are surjective.

### 5. Color-mixing operads and family algebraic structures

We follow the lines of [2, Section 2], except that we consider gradings taking values in an arbitrary set \( \Omega \) rather than in a semigroup. The key point is that if an algebraic structure on a graded object is compatible with the grading in a natural sense, this algebraic structure in turn provides an algebraic structure on \( \Omega \). For example, a degree-compatible associative algebra structure on a graded object yields a semigroup structure on \( \Omega \), a degree-compatible dendriform (resp. duplicial) algebra structure on a graded object yields a diassociative (resp. duplicial) semigroup structure on \( \Omega \), and so on.

#### 5.1. Color-mixing operads: the principle

Let \( \Omega \) be a set of colors and \( \mathcal{C} \) be a bicomplete monoidal category. Keeping the notations of Paragraphs 3.3 and 3.4, for any operad \( \mathcal{P} \), all components \( \mathcal{P}_{A,\alpha,\omega}^\Omega \) of the colored operad \( \mathcal{P}^\Omega \) are isomorphic once the finite set \( A \) of inputs is fixed. This reflects the fact that, if a \( \mathcal{P} \)-algebra \( V \) is a coproduct

\[
V = \bigsqcup_{\omega \in \Omega} V_{\omega},
\]

any operation \( \mu : V^{\otimes A} \to V \) with \( A \)-indexed inputs has a priori nonzero components

\[
\mu_{\underline{\alpha},\omega} : \bigotimes_{a \in A} V_{\omega(\alpha)} \longrightarrow V_{\omega}
\]

for any \( \underline{\alpha} \in \Omega^A \) and \( \omega \in \Omega \). This clearly contradicts the principle outlined in the introducing paragraph of this section, according to which the graded object \( V = (V_{\omega})_{\omega \in \Omega} \) should be not only a \( \mathcal{P}^\Omega \)-algebra, but also a ”graded \( \mathcal{P} \)-algebra” in some sense. This means that the output color \( \omega \) should be a combination of the input colors \( \underline{\alpha} \) in a way prescribed by the operad \( \mathcal{P} \).
5.2. Color-mixing linear operads. From now on, we stick to the case when $\mathcal{C}$ is the category of vector spaces over some field $k$. The coproduct is now given by the usual direct sum $\oplus$. Guided by the dendriform and the pre-Lie examples detailed in the previous sections, we see that the color set $\Omega$ will be endowed with a $\mathcal{P}_j$-algebra structure, where $\mathcal{P}_j$ is a set operad derived from the linear operad $\mathcal{P}$. For example, if $\mathcal{P}$ is the dendriform operad, $\mathcal{P}_j$ is the diassociative operad, and if $\mathcal{P}$ is the pre-Lie operad, $\mathcal{P}_j$ is the Perm operad. When $\mathcal{P}$ is the linearization of a set operad $\mathcal{P}$, we should get $\mathcal{P}_j = \mathcal{P}$, as the duplicial example suggests.

We suppose that $\mathcal{P}$ is of finite presentation, i.e. it can be written as

$$\mathcal{P} = \mathcal{M}_E/R,$$

where $E$ is a set species of generators, $\mathcal{M}_E$ is the free set operad generated by $E$, and $R$ is the operadic ideal of the linear operad $\mathcal{M}_E = k \cdot \mathcal{M}_E$ generated by a finite linearly independent collection $\mu^1, \ldots, \mu^N$ of elements. Each of these elements can be written as

$$\mu^i = \sum_{j=1}^k \lambda^i_j \mu^j,$$

where $(\mu^j)_j$ is a linearly independent collection of monomial expressions involving elements of $E$ and partial compositions, and $\lambda^i_j \in k - \{0\}$.

**Definition 5.1.** The set operadic equivalence relation generated by $R$ is the finest equivalence relation $R_j$ on $\mathcal{M}_E$, compatible with the set operad structure, such that

$$\mu^i p \sim_{R_j} \mu^i q$$

for any $i \in \{1, \ldots, N\}$ and $p, q \in \{1, \ldots, k_i\}$.

The set operad associated to $\mathcal{P}$ is the set operad

$$\mathcal{P}_j := \mathcal{M}_E/R_j.$$

**Remark 5.2.** The set operad $\mathcal{P}_j$ depends on the presentation chosen for the linear operad $\mathcal{P}$. When $\mathcal{P}$ is given by the linearization of a set operad $\mathcal{P}$, we have $\mathcal{P}_j = \mathcal{P}$.

**Remark 5.3.** Let $\mathcal{Q}$ be a quadratic set operad, and let $\mathcal{P}$ be the Koszul dual [11] of its linearization. If $E = \mathcal{Q}_2$, the free set-operad $\mathcal{M}_E$ generated by $E$ is combinatorially represented by binary trees which leaves are indexed and vertices decorated by elements of $E$. Let $\sim$ be the equivalence on $\mathcal{M}_E(3)$ such that $\mathcal{M}_E(3)/\sim = \mathcal{Q}(3)$. By definition of the Koszul dual, $\mathcal{P}$ is generated by $E$, and the relations

$$\sum_{T \in C} \pm T = 0,$$

where $C$ is a class of $\sim$ and the signs $\pm$ depend only of the form of the tree. Applying Definition 5.1, we obtain that $\mathcal{P}_j = \mathcal{Q}$. This holds for example if $\mathcal{Q}$ is the associative, or permutative, or diassociative operad: then $\mathcal{P}$ is the operad of, respectively, associative, or pre-Lie, or dendriform algebras, with their usual presentations.

**Proposition 5.4.** Let $\Omega$ be a set endowed with a $\mathcal{P}_j$-algebra structure. Considering the $\mathcal{M}_E$-algebra structure on $\Omega$ given by the operad morphism $\otimes : \mathcal{M}_E \to \mathcal{P}_j$,

(a) The colored subspecies $\tilde{\mathcal{M}}^\Omega_E$ of $\mathcal{M}_E^\Omega$ defined by

$$(\tilde{\mathcal{M}}^\Omega_E)_{\lambda, \omega} := \{ \mu \in (\mathcal{M}_E)_A, \mu(\lambda) = \omega \}$$

is a set colored suboperad of $\mathcal{M}_E^\Omega$. 
(b) The colored subspecies \( \tilde{M}_E^\Omega \) of \( M_E^\Omega \) defined by
\[
(\tilde{M}_E^\Omega)_{A,\alpha,\omega} := k \cdot (M_E^\Omega)_{A,\alpha,\omega}
\]
is a linear colored suboperad of \( M_E^\Omega \).

(c) The colored subspecies \( \mathcal{J} \) of \( M_E^\Omega \) defined by
\[
\mathcal{J}_{A,\alpha,\omega} := k \cdot \{ \mu \in (M_E^\Omega)_A, \mu(\alpha) \neq \omega \}
\]
is a right colored operadic ideal, and the quotient \( M_E/\mathcal{J} \) is isomorphic to \( \tilde{M}_E^\Omega \) as a colored species.

**Proof.** Let \((A, \alpha, \omega)\) and \((B, \beta, \zeta)\) be two \( \Omega \)-colored finite sets. Let \( \mu \in (\tilde{M}_E^\Omega)_{A,\alpha,\omega} \) and \( \nu \in (\tilde{M}_E^\Omega)_{B,\beta,\zeta} \).

We have then by definition of \( \tilde{M}_E^\Omega \),
\[
\mu(\alpha) = \omega \quad \text{and} \quad \nu(\beta) = \zeta.
\]

Now let \( a \in A \). The partial composition \( \mu \circ_a \nu \) is defined in the colored operad \( M_E^\Omega \) if and only if \( \zeta = \alpha(a) \). In that case we obviously have
\[
\omega = \mu(\alpha) = (\mu \circ_a \nu)(\alpha \sqcup_a \beta),
\]

hence \( \mu \circ_a \nu \in (\tilde{M}_E^\Omega)_{A \sqcup_a B, \alpha \sqcup_a \beta, \omega} \). The second assertion is an immediate consequence of the first.

Now let \( \mu \in (M_E^\Omega)_A \) and \( \nu \in (M_E^\Omega)_B \) where \( A \) and \( B \) are two finite sets, and choose \( a \in A \). The partial composition \( \mu \circ_a \nu \) vanishes in \( M_E^\Omega \) unless the color matching condition \( \zeta = \alpha(a) \) is verified. If \( \mu \in \mathcal{J} \), then by definition \( \mu(\alpha) \neq \omega \), hence
\[
(\mu \circ_a \nu)(\alpha \sqcup_a \beta) = \begin{cases} 
(\mu(\alpha)) & \text{if } \zeta = \alpha(a) \\
0 & \text{if not,}
\end{cases}
\]

hence \( \mu \circ_a \nu \in \mathcal{J} \). The last assertion is obvious from the definition. \( \square \)

We denote by \( \mathcal{J} \) the two-sided colored operadic ideal of \( M_E \) generated by \( \mathcal{J} \). The following corollary is immediate:

**Corollary 5.5.** Let \( \pi \) be the projection from the free linear operad \( M_E \) onto \( \mathcal{P} \), and let \( \overline{\mathcal{P}} \) be the projection from \( M_E \) onto \( k \cdot \mathcal{P} \). Suppose that \( \Omega \) is a \( \mathcal{P} \)-algebra. Then the colored subspecies \( \overline{\mathcal{P}}^\Omega := \pi(M_E^\Omega) \) of \( \mathcal{P}^\Omega \) is a linear colored suboperad of \( \mathcal{P}^\Omega \), and \( \pi(\mathcal{J}) \) is a two-sided colored operadic ideal of \( \mathcal{P}^\Omega \).

**Definition 5.6.** The colored operad \( \overline{\mathcal{P}}^\Omega := \mathcal{P}/\pi(\mathcal{J}) \) is the **color-mixing operad** associated to the operad \( \mathcal{P} \). It does depend on the presentation \( \mathcal{P} = M_E/\mathcal{R} \), and supposes a \( \mathcal{P} \)-algebra structure on \( \Omega \).

**Remark 5.7.** The notion of color-mixing operad was already approached in the case when \( \Omega \) is a commutative semigroup : an \( \Omega \)-colored operad in which the output color is the sum of the input colors was given the name **current-preserving operad** in [18]. The colored suboperad \( \overline{\mathcal{P}}^\Omega \) associated to any ordinary operad \( \mathcal{P} \) is an example.

**Remark 5.8.** The right ideal \( \mathcal{J} \) is not two-sided in general, hence the color-mixing operad \( \overline{\mathcal{P}}^\Omega \) is in general a proper quotient of the colored suboperad \( \overline{\mathcal{P}}^\Omega \).
5.3. Graded algebras over a color-mixing operad and family structures. Let \( \Omega \) be a set, let \( k \) be a field, and let \( \mathcal{P} \) be an operad in the category of \( k \)-vector spaces. We keep the notations of the previous paragraphs, and in particular we fix a finite presentation \( \mathcal{P} = \mathcal{M}_E \mathcal{R} \).

**Definition 5.9.** An \( \Omega \)-graded \( \mathcal{P} \)-algebra is an algebra over the \( \Omega \)-colored operad \( \widetilde{\mathcal{P}} \), i.e. an \( \Omega \)-graded \( k \)-vector space \( V \) together with a morphism of colored operads \( \Phi : \widetilde{\mathcal{P}} \rightarrow \text{End}(V) \).

Let us remark that the notion of \( \Omega \)-graded \( \mathcal{P} \)-algebra depends on the presentation of the operad \( \mathcal{P} \).

**Proposition 5.10.** Any \( \Omega \)-graded \( \mathcal{P} \)-algebra \( V \) is an algebra over both colored operads \( \mathcal{P} \) and \( \widetilde{\mathcal{P}} \).

**Proof.** It is an immediate consequence of the following diagram of \( \Omega \)-colored operads:

\[
\begin{array}{ccc}
\widetilde{\mathcal{P}} & \rightarrow & \mathcal{P} \\
\rightarrow & & \rightarrow \\
& \mathcal{P} \Omega & \rightarrow & \text{End}(V).
\end{array}
\]

\( \square \)

We are now ready to define \( \Omega \)-family \( \mathcal{P} \)-algebras, also called \( \Omega \)-relative \( \mathcal{P} \)-algebras in M. Aguiar’s terminology [2, Definition 14]:

**Definition 5.11.** An \( \Omega \)-family \( \mathcal{P} \)-algebra is an \( \Omega \)-graded \( \mathcal{P} \)-algebra for which the underlying \( \Omega \)-graded object is uniform.

Again, this notion depends on the presentation of \( \mathcal{P} \).

**Proposition 5.12.** Any \( \Omega \)-family \( \mathcal{P} \)-algebra is an \( \Omega \)-graded vector space \( \mathcal{U}(V) \), where \( V \) is an algebra over the operad \( \mathcal{F}(\mathcal{P}) \).

**Proof.** By definition, an \( \Omega \)-family \( \mathcal{P} \)-algebra is given by a vector space \( V \) and a colored operad morphism \( \Phi : \mathcal{F}(\mathcal{P}) \rightarrow \text{End}(\mathcal{U}(V)) \).

We have \( \text{End}(\mathcal{U}(V)) = \mathcal{U}(\text{End}V) \) by Equation (39). The functor \( \mathcal{U} \) of the left- (resp. right-) hand side is defined in Paragraph 3.4 (resp. 3.3). The functor \( \mathcal{U} \) is right-adjoint to the completed forgetful functor \( \mathcal{F}(\mathcal{P}) \) defined in Paragraph 3.3, hence there is a morphism of ordinary operads from \( \mathcal{F}(\mathcal{P}) \) to \( \text{End}V \).

Finally, we recover the close link between algebras and family algebras which was already observed on the known examples, and established by M. Aguiar in the case when \( \Omega \) is a semigroup [2, Paragraph 2.4]:

**Proposition 5.13.** Let \( V = \mathcal{U}(V) \) be an \( \Omega \)-family \( \mathcal{P} \)-algebra. Then the vector space \( \mathcal{F}\mathcal{U}(V) = V \otimes k\Omega \) is a \( \mathcal{P} \)-algebra.

**Proof.** From Proposition 5.10, \( V = \mathcal{U}(V) \) is an algebra over \( \mathcal{P} \mathcal{O} = \mathcal{U}(\mathcal{P}) \). We have then a colored operad morphism

\[
\Phi : \mathcal{U}(\mathcal{P}) \rightarrow \text{End}(\mathcal{U}(V)) = \mathcal{U}(\text{End}V).
\]

Now the functor \( \mathcal{U} \) is left-adjoint to the forgetful functor \( \mathcal{F} \), hence there is an operad morphism

\[
\Psi : \mathcal{P} \rightarrow \mathcal{F}\mathcal{U}(\text{End}V).
\]
We conclude by the following observation: for any finite set $A$ we have
\[(\mathcal{F}\mathcal{U}(\text{End} V))_A = \bigoplus_{\alpha \in \Omega^4, \omega \in \Omega} (\text{End} V)_A \bigoplus_{\omega \in \Omega} \prod_{\alpha \in \Omega} (\text{End} V)_A = \text{End}(\mathcal{F}\mathcal{U}(V))_A.\]

These inclusions $j_A$ yield an operad morphism $j$, hence $j \circ \Psi$ is an operad morphism from $\mathcal{P}$ to $\text{End}(\mathcal{F}\mathcal{U}(V))$. □
